Fourteen patients who had previous hypertensive cerebral accidents were maintaining normal blood-pressure levels five to eleven years after operation.

Approximately a third of the entire series suffered a recurrence of cerebrovascular accident during the long period subsequent to neurosurgical treatment, and 50 per cent of the deaths were caused by such recurrences.

Interval Between Apoplexy and Splanchnicectomy

As long as the sympathectomy was performed within two years of the cerebral accident, post-operative survival was not appreciably influenced. But the 53 per cent five-year survival rate in the 30 cases in which two to four years elapsed between the stroke and the operation was definitely lower than that of the remainder of the series.

Factors of No Influence on Postoperative Survival

The presence of headaches, the occurrence of epistaxes, the neurologic findings subsequent to the

per cent, there has been no significant change from the preoperative diastolic-blood-pressure levels. Seventy patients, or the remaining 52 per cent of the series, are now dead, five to fourteen years after splanchnicectomy.

RATIONALE OF SPLANCHNICECTOMY

The influence of splanchnicectomy upon the cerebral circulation is an indirect one, for the operation does not denervate the cerebral arterial bed. Whatever benefit patients with hypertensive cerebrovascular disease may derive from a symp-

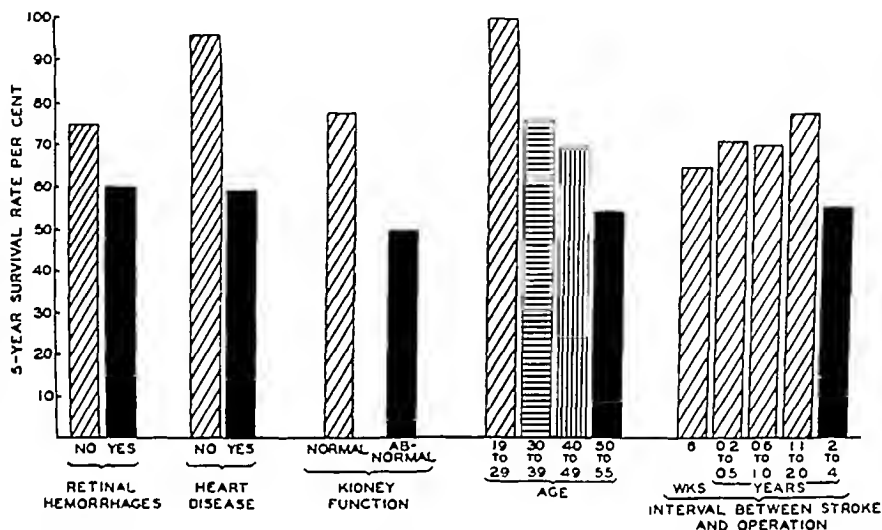

FIGURE 3 Factors Influencing Five-Year Survival Rate of 135 Patients with Hypertensive Cerebrovascular Disease Treated by Splanchnicectomy

cerebral accident, the complaint of vertigo and the known duration of elevated blood pressure prior to operation exerted no significant influence on the survival of the patients in this series.

BLOOD PRESSURE AFTER SPLANCHNICECTOMY

The 65 patients still living five to thirteen years after splanchnicectomy performed subsequent to a cerebral accident have recently been examined. Fourteen, or 10.4 per cent of the entire series, are maintaining normal blood-pressure levels of less than 150 systolic, 90 diastolic. Two of the patients maintaining normal blood-pressure levels were operated upon in 1937, each six months after a cerebrovascular accident, and the preoperative blood-pressure levels averaged 225 systolic, 148 diastolic, and 185 systolic, 120 diastolic, respectively.

In 41 cases, or 30.3 per cent of the entire series, significant reductions of 20 mm or more from the preoperative diastolic pressure have been maintained for five to thirteen years. In 10 cases, or 7.3

thectomy must thus stem from an improvement in the general circulation following operation.

It has been demonstrated in this series that the persons who continue to live a long time after splanchnicectomy without recurrence of cerebral accidents also continue to maintain significant reduction of their blood pressure, with only a few exceptions. In a previous study of cardiac aspects in cases of arterial hypertension treated by splanchnic resection,¹¹ it was found that there was significant improvement in electrocardiograms and decrease in heart size after operation.

In recent years it has been realized that certain dynamic, functional factors are involved in the production of brain-tissue damage from vascular causes. In addition to the occurrence of the histologic changes of hyalinization and thickening of cerebral blood vessels in hypertension, superimposed disturbances in the general circulation are responsible for the cerebrovascular accidents in this disease.

The reduction of blood pressure, the improvement of cardiac status and the decrease in pressor response to emotional and other stimuli after splanchnicectomy reflect the improvement in the general circulation that occurs in some cases. This approach to the cerebral circulation via the general circulation seems reasonable, until a more effective measure is available for long-range treatment of hypertensive cerebrovascular disease.

DISCUSSION

As yet no definite statement can be made whether the surgical procedure of splanchnicectomy has beneficially altered the course and prolonged the lives of patients with hypertensive cerebrovascular disease. The literature does not contain a sizable series of hypertensive patients followed after surviving a cerebral accident. No control group is available for a proper comparison.

That some patients with hypertensive cerebrovascular disease pursue a rather rapid downhill course with a short duration of life is pointed out by Taylor and Page.¹² They studied 40 patients who died of hypertensive disease (19 of cerebral hemorrhage) to uncover facts that might aid in predicting whether a patient with essential hypertension is likely to have a stroke. Five findings were especially common among those who died of cerebral hemorrhage: severe headache, vertigo or syncope, motor or sensory neurologic disturbance, epistaxis and retinal hemorrhages. Those who died of cerebral hemorrhage lived an average of two years and one month after the first symptom of the ultimate cause of death, the duration of life from the appearance of the first neurologic sign averaged only a year and a half.

Newbill¹³ determined the duration of life after cerebrovascular accidents in 296 cases found in the 10,903 consecutive autopsies performed at Charity Hospital, New Orleans, between 1929 and 1938. Only 16.9 per cent of patients lived one month or longer after apoplexy, and only 1 survived longer than a year. Naturally, studies based on autopsy reports can only present the most unpleasant view of a clinical picture.

The survival statistics of our series of hypertensive patients with cerebrovascular disease treated by splanchnicectomy appear good, but decision whether the operation has beneficially modified the course of this aspect of hypertensive disease must await valid comparison with an appropriate control. The ultimate worth of the neurosurgical treatment of arterial hypertension can best be evaluated by determination of its influence on the natural life history of this disease.

SUMMARY

The surgical procedure of bilateral supradiaphragmatic splanchnicectomy has been utilized in the treatment of 135 hypertensive patients who had already sustained a definite cerebrovascular accident, in the attempt to alter beneficially the course of their disease.

These patients have now been followed for a long time, and it has been found that the five-year survival rate for the entire series (in which male patients predominate) was 67.3 per cent, and that the ten-year survival rate was 40.5 per cent. The female patients had better survival rates than the males.

Survival in hypertensive cerebrovascular disease is adversely influenced by the presence of retinal hemorrhages, high diastolic blood pressure and heart disease, the coincidence of impaired kidney function, the advancing age of the patient and an interval of longer than two years between the stroke and the splanchnicectomy.

Fourteen patients who had previous hypertensive cerebral accidents were maintaining normal blood-pressure levels five to eleven years after operation.

Approximately a third of the entire series suffered a recurrence of cerebrovascular accident during the long period subsequent to neurosurgical treatment, and 50 per cent of the deaths were caused by such recurrences.

PUBLIC FINANCING OF MEDICAL EDUCATION, RESEARCH, HEALTH AND MEDICAL CARE*

ALLAN M BUTLER, M D †

BOSTON

DISCUSSION of the bills pertaining to medical education, research, health and medical care that are now before the Congress indicates a considerable public interest in these matters. The increase in the effectiveness of modern medicine and in the cost of medical care has forced this interest upon the public. The public is not only interested as consumer but also as financier. The fact that in 1946 the public through Government contributed some \$1,200,000,000 for health and medical care is a measure of the failure of philanthropy and private charity to meet the needs.

The increase in the number of hospitals over the country at large faced with bankruptcy and in the number of medical schools having difficulty balancing their budgets has emphasized the need of financing medical care and education in a more systematic manner than in the past. When we are still in a period of inflation, when the country is seriously short of physicians and when medical education must be both expanded and improved if the medical needs of the people are to be satisfied, some of the wealthiest medical schools are being forced to curtail their budgets and most teaching hospitals in the country are faced with an annual deficit that threatens solvency. One of the large teaching hospitals in the past year had a deficit approximating one million dollars.

In the last few years, the opposition to Government as the logical agency in a democracy to collect funds from the public for medical education and research and from those whose health permits productive effort to finance those who suffer the misfortune of illness has lessened markedly. The public and the American Medical Association have within the past few years approved Government financing of hospital construction on a national basis, Government financing of medical education and medical research by grants from the Federal Security Agency and the proposed National Research Foundation, Government extending its support of maternal and child care through the Children's Bureau of the Federal Security Agency, and Government extension of public-health services. The American Medical Association has also, in endorsing the Taft National Health Act of 1947, approved Government financing of medical care for

low-income groups. Incidentally, the approval of these five things means that the American Medical Association has now endorsed five of the six parts of the original Wagner-Murray-Dingell Bill. In view of the bitter denunciation of this bill by the medical profession, endorsement of so much of the original bill is indeed noteworthy.

The question before us today, therefore, is not whether we will or will not have Government-financed medical care, it is rather how Government-financed medical care will be accomplished.

Must it continue in the more or less haphazard manner by which it has been accomplished up to date, or can it be done in a more orderly and coordinated manner?

Mr. Bernard Baruch, speaking in November to the County Medical Societies and Hospital Association of New York City, said

There is no question — the need for more medical care exists. Also, there is no question this need will have to be met. The problem is how.

In the matter of adequate medical care, too many doctors have been fighting a rear-guard action for too long. I feel I must warn those doctors — time is running against them. The medical profession has justly earned great influence in the community. It can keep that hold only as it moves forward. It will lose that hold if it has nothing but objections to offer, if it has eyes only for what not to do.

We must look for what can be done — and do it.

The great question is how? I do not want to seem to say I know the answers. We do know the public is demanding better and more medical service through some action — political or otherwise.

Even the least ambitious schemes for improving the nation's health require more doctors, all competently trained. Why aren't more doctors being educated? In studying that question, I was struck by how expensive training a doctor has become — in dollars and in time.

Professor Edwards A. Park, emeritus professor of pediatrics, at Johns Hopkins University School of Medicine, speaking at the New York Academy of Medicine in the spring of 1948, stated

The private medical schools must have state aid. At Johns Hopkins the tuition is \$600.00 a year. The cost to the medical school of the education of the student is \$3,900 per year. With the shrinking resources and the disappearance of the old private supports and without the addition of new, the full-time medical schools cannot continue.

The State must aid the student financially, because of the long, costly preliminary years of preparation, if medicine is to attract the finest of our young men. During four years in Johns Hopkins Medical School, the cost of the expenses of the medical student, apart from tuition, is from \$1,300 to \$1,500 a year. During his hospital training as intern, he receives no stipend. Only to those who command financial resources and can wait the years of preparation is a medical career open.

*Presented at a meeting of the Suffolk District Medical Society as part of a symposium on Current Congressional Medical Legislation. Harvard Club of Boston, May 1, 1948.

†Professor of pediatrics, Harvard Medical School, chief Children's Medical Service, Massachusetts General Hospital.

The New York Academy of Medicine's report on "Medicine in the Changing Order" states

There seems no alternative other than government aid if educational standards are to be raised or even maintained. If medical schools are to continue as centers of research here also government aid may be necessary.

A beginning is being made in such financing of medical education and research under existing legislation through the United States Public Health Service and the National Institute of Health. The bill pertaining to financing medical education that has recently been introduced in the Congress is the most recent development. Thus far the manner in which admirably qualified committees have approved the applications for scholarships or grants to support teaching and research has given little ground for criticism. Will the Congress defend the professional direction of this federal support or will it permit its members or members of the administrative branch of the Government to channel the grants to specified fields of medicine that have a popular appeal? If so, Government-financed medical education and research may be as compartmentalized by sentimental appeal as is the research financed by the high-pressure drives for infantile paralysis, cancer and, recently, heart disease. The bill pertaining to heart disease certainly demands careful thought. If we start piecemeal, according to the dictates of pressure groups without due thought, the possibility of systematically financing medical research on a broad co-ordinated basis by Government support may be postponed for years.

As a pediatrician I am particularly interested in improving the training of physicians in the health and medical care of infants and children. The recommendations of the Executive Committee of the American Academy of Pediatrics concerning federal support of pediatric teaching were based on a survey recently completed, under the joint auspices of the American Academy of Pediatrics, the United States Public Health Service and the Children's Bureau, of the facilities for training physicians in the care of infants and children in the United States. Dr John A. Toomey, president of the Academy, reports that this survey "has revealed a critical need of funds for the support of pediatric departments in the medical schools and the improvement of pediatric teaching of medical students." The Committee for the Improvement of Child Health and the Executive Board of the American Academy of Pediatrics have, therefore, submitted a recommendation for federal support of pediatric education. The report states

The preliminary findings of the Study reveal a startling lack of adequate training of a considerable portion of both general practitioners and pediatricians.

General practitioners provide 75 per cent of the medical care of the children of the country. Yet nearly half (46 per cent) have had practically no hospital training in pedi-

atrics, 16 per cent have reported that they had no hospital training whatsoever following graduation from medical school.

These facts now being sharply defined by the Academy's Study point directly to the need for more physicians who are trained in the care of children, especially in the remote and rural areas. This need must be met before other health measures can be effected.

This need can be met only by strengthening pediatric education in medical schools and hospitals, for undergraduates and postgraduates, for general practitioners and pediatricians, and by bringing the benefit of this teaching to the child wherever he is.

Personal visits to each of the seventy approved medical schools and their affiliated hospitals have brought into clear focus the precarious financial situation which limits pediatric education today. The average budget for the pediatric departments of the seventy medical schools is approximately \$25,000 a year. Over a third of the pediatric departments work on teaching budgets of less than \$10,000 a year, three of these have no regularly allocated funds for teaching.

Federal support for child health training is required to provide more physicians, both general practitioners and specialists, better trained in the medical care and health supervision of children from birth to adolescence, as a means toward making available to all children of this country a more equitable distribution of health services of high quality.

The presentation of this considered report to Academy members has produced a rather violent reaction from some quarters. In a letter to Dr Toomey, Dr W. C. Black, of the Association of American Physicians and Surgeons, said,

I cannot tell you how stunned and staggered I was as I read this vicious document which has received official approval by our Executive Board. I could not believe my eyes. Now that I have recovered from the initial shock somewhat, I wish to inform you of my complete, total, uncompromising disgust with this stupid and visionary report, and the clear implication that control of Academy affairs and of the pediatric survey have fallen into the hands of persons committed to the collectivist social philosophy.

This is a fair example of the vehemence with which doctors can say what not to do. It reminds one of the editorials that appeared in the *Journal of the American Medical Association* in 1937 damning the Committee of Physicians and the 430 endorsers for advocating federal support of medical education and research. Not only were these physicians called followers of Communist philosophy in those editorials but also they were asked to make a public apology for and retraction of their statement.

The antipathy of many Americans to genuine planning is interesting. Today, perhaps half the budgets of medical schools and half the sums expended on medical research are provided by Government. The public accepts all this governmental financing of medical research and education if it is done without much over-all planning. The same attitude applies to medical care. It is all right for the United Mine Workers to establish separate health and medical services for its members. It is all right for the Garment Workers to establish clinic, but not home or hospital medical services. The United Automobile Workers may establish a diagnostic service provided they do not follow

PUBLIC FINANCING OF MEDICAL EDUCATION, RESEARCH, HEALTH AND MEDICAL CARE*

ALLAN M. BUTLER, M.D.†

BOSTON

DISCUSSION of the bills pertaining to medical education, research, health and medical care that are now before the Congress indicates a considerable public interest in these matters. The increase in the effectiveness of modern medicine and in the cost of medical care has forced this interest upon the public. The public is not only interested as consumer but also as financier. The public and the American Medical Association have within the past few years approved Government financing of hospital construction on a national basis, Government financing of medical education and medical research by grants from the Federal Security Agency and the proposed National Research Foundation, Government extending its support of maternal and child care through the Children's Bureau of the Federal Security Agency, and Government extension of public-health services. The American Medical Association has also, in endorsing the Taft National Health Act of 1947, approved Government financing of medical care for

low-income groups. Incidentally, the approval of these five things means that the American Medical Association has now endorsed five of the six parts of the original Wagner-Murray-Dingell Bill. In view of the bitter denunciation of this bill by the medical profession, endorsement of so much of the original bill is indeed noteworthy.

The question before us today, therefore, is not whether we will or will not have Government financed medical care, it is rather how Government-financed medical care will be accomplished.

Must it continue in the more or less haphazard manner by which it has been accomplished up to date, or can it be done in a more orderly and coordinated manner?

Mr. Bernard Baruch, speaking in November to the County Medical Societies and Hospital Association of New York City, said

There is no question — the need for more medical care exists. Also, there is no question this need will have to be met. The problem is how.

In the matter of adequate medical care, too many doctors have been fighting a rear-guard action for too long. I feel I must warn those doctors — time is running against them. The medical profession has justly earned great influence in the community. It can keep that hold only as it moves forward. It will lose that hold if it has nothing but objections to offer, if it has eyes only for what not to do.

We must look for what can be done — and do it.

The great question is how? I do not want to seem to say I know the answers. We do know the public is demanding better and more medical service through some action — political or otherwise.

Even the least ambitious schemes for improving the nation's health require more doctors, all competently trained. Why aren't more doctors being educated? In studying that question, I was struck by how expensive training a doctor has become — in dollars and in time.

Professor Edwards A. Park, emeritus professor of pediatrics, at Johns Hopkins University School of Medicine, speaking at the New York Academy of Medicine in the spring of 1948, stated

The private medical schools must have state aid. At Johns Hopkins the tuition is \$600.00 a year. The cost to the medical school of the education of the student is \$3,900 per year. With the shrinking resources and the disappearance of the old private supports and without the addition of new, the full-time medical schools cannot continue.

The State must aid the student financially, because of the long, costly preliminary years of preparation, if medicine is to attract the finest of our young men. During four years in Johns Hopkins Medical School, the cost of the expenses of the medical student, apart from tuition, is from \$1,300 to \$1,500 a year. During his hospital training as intern, he receives no stipend. Only to those who command financial resources and can wait the years of preparation is a medical career open.

†Professor of pediatrics, Harvard Medical School; chief, Children's Medical Service, Massachusetts General Hospital.

Wagner, Murray, Truman and Baruch being unionists

Taft National Health Act states, as you know, "that it is the policy of the United States to have the States, through consultative services and grant-in-aid, to make available medical, hospital, dental and public-health services to every individual regardless of race or economic status" This will be accomplished under state-wide programs that will provide "(a) hospital services, surgical services and medical services for all those families and individuals in the State having insufficient income to bear the whole cost of such, and (b) periodic physical examinations for all children in elementary and secondary schools in the State" And it is further specified "Such program shall provide for collection of proper charges of less than the actual cost of such services from persons unable to pay in whole, but able to pay in part therefor" The federal contribution to the costs of these programs will come from general tax funds. Each State is left to collect its portion of the costs as it best fits. No mention is made in the bill of definition of eligibility other than mention that the services are to be provided for families and individuals with low incomes. So the question of whether this bill is intended for 20 per cent or 70 per cent of the cost is left open. Eligibility, however ultimately defined, will have to be reassessed continually according to the shifting earning capacity and expenses as affected by employment and illness. And each time the eligibility will have to be defined in terms of the Government's contributing 10, 25, 50, 75 or 100 per cent of the costs of the care at the moment. Thus, the bill provides "free medicine" to an indefinitely and difficultly defined portion of the public. Moreover, the federal Government is denied means of defending the quality of this free medicine. Finally there is no provision for improving medical care by supporting medical education and research except for some very inadequate support for dental research. The following is Dr. Park's opinion of the bill.

If the bill were passed as it stands, there could be as many different systems of medical care as there are states. Some of these in the more progressive states would probably be very good, in some other states exceedingly poor, and all would be laid open to the possibility of political intrigue and inefficiency. If the passage of the Wagner-Murray-Dingell Bill would produce chaos in medical care, the Taft Bill would produce national confusion and perhaps corruption, and would establish an inefficiency which it might be impossible to overcome. It would span the way to the perpetuation and extension of the poor features of the present system of medical care without the assurance of new good features. The bill is an example of careless thinking, or not thinking at all, and the fact that such a manifestly inferior measure could be proposed by our legislators is depressing to those who perceive how glorious a medical care program might be.

In an article in the *Yale Review*, ex-Governor Arnall states

There is a wide gulf between the proposals of some liberals for universal medical care and the proposals of some Radical Tories for subsidization of medical costs in the lower-income groups, a form of Bismarckian State Socialism repugnant to all American concepts, however well intended and however beneficial to the subsidized groups at the expense of the main body of citizens.

The Democratic party can, with propriety, support a measure, such as President Truman recommends, to include the cost of medical care in the general Social Security program of the country. The desirability of a specific measure would depend upon the cost of the program, the details of administration, etc. But, in theory, there is nothing objectionable about such a program. On the other hand, a program to subsidize medical care of those who are in depressed groups, to establish such a subsidy as a national policy and thereby give aid and comfort to those who believe that a handout is the appropriate substitute for justice, is not in accord with the basic beliefs of those who think that America can fulfill its promises of individual freedom and social responsibility.

Neither the National Health Insurance Act (S 1320) nor the Taft National Health Act (S 545) is compulsory regarding use of provisions by the public or participation by doctors. Both provide compulsion for collection of funds from the public. Indeed, the compulsion is similar to that pertaining to public education. Hence the designation of the former as a compulsory program and the latter as a voluntary one appears odd. Under both bills the federal Government's role is largely collection and allocation of funds. Under S 1320 there are a few provisions whereby the federal board with the advice and consent of the advisory council may designate standards in the interest of quality of care and efficiency of service. This kind of federal administration of grant-in-aid programs to states has been going on for years. The charge that either of these national health programs would establish a federal autocracy that would dominate American medicine and a federal bureaucracy that would bog it down seems to miss the serious administrative difficulties. The serious administrative problems under either bill will be at the state and local levels rather than the federal level.

In using these two bills as examples of the divergent manner in which Government financing of medical care may be approached and the emotional reactions that this problem may evoke, my personal point of view may be apparent. That however is not important. What is important is that we are at the crossroads where the decision must be made to proceed either along the way of a broad, clearly defined policy of more adequately financing medical education, research and care or along the way of ill defined temporary expediency. The former will require considered thought, tolerant discussion and much public debate. Diversity of opinion should be not only expected but also encouraged. For as President Conant of Harvard remarked in his annual report of this year, "In a democracy with our traditions only those reasoned convictions which emerge from diversity of opinion can lead to that unity — so essential for the welfare of the country." In this connection the medical

diagnosis with treatment The American Medical Association will endorse Senator Saltonstall's school health services bill, if it is limited to physical examination and does not include treatment of needs detected by the examination Apparently, almost anything is all right as long as effort is divided, uncoordinated and inefficient, and as long as one does not undertake to do a systematic job in providing health and medical care for the American people Is it that we are afraid of our ability to tackle the real job, or are we afraid of what doing the job successfully would mean? As I have already suggested, should we not rather be afraid of what legislation without considered thought and planning may do?

I do not wish to argue here the pros and cons of the National Health Insurance Act of 1948 (S 1320) vs the National Health Act of 1948 (S 545) But in terms of considered planning vs temporary expediency the two measures may serve as examples

When the original Wagner-Murray-Dingell Bill was first discussed much thought was given to whether medical care should be financed from general tax funds or by application of the insurance principle The more radically inclined favored financing medical care from general tax funds This, they said, applied the principle of progressive taxation and continued the present policy of the rich paying for the medical care of the poor The representatives of labor, however, argued that this was in a sense too socialistic It meant that the lower-income groups would be getting "free medicine" It also meant that most of the public would not directly feel the cost or be aware of it It was argued that application of the insurance principle by payroll deduction was sounder This, it was said, would mean that all labor or gainfully occupied people would be conscious of the cost of the governmentally financed medical care Having visibly paid their money they would insist upon getting their money's worth This would be an excellent check on the economy and efficiency of the services They also emphasized that application of the insurance principle by payroll deduction would automatically designate those whose medicine would have to be financed from general tax funds For obviously all persons against whom payroll deductions were not made would of necessity be needy persons who had to have their medical care paid for by others

The group arguing for application of the insurance principle by payroll deduction won So the Wagner-Murray-Dingell Bill (the National Health Insurance Act of 1948) avoided a "means test" that would be costly in administration and open to all kinds of political pressures at the local administrative levels concerning eligibility Apparently Mr Baruch agrees with this conservative decision by those drawing up the Wagner-Murray-Dingell Bill In the address referred to above, he states

Your [that is, doctors'] organizations have been particularly active in pressing voluntary health insurance You and others have proven group insurance to be a so practical way That is a great achievement. You can't be proud of it

But I would not be frank — nor friendly — if I did add what you know It is not good enough

Rome was not doctored in one day It may be, as I have told me, that the needs of the bulk of our people can be met, given time, through voluntary insurance What troubles me most are the needs of that sizable segment of society which does not earn enough to pay for voluntary insurance

Nothing has been suggested so far, which promises success, other than some form of insurance covering the people in by law and financed by the Government, at least in part — what some would call "compulsory health insurance"

As to financing, my own preference runs toward Government meeting only part of the cost, with part coming from payroll deductions from employers and workers.

The detailed problems raised by so-called compulsory health insurance are too numerous to be discussed tonight. I have weighed them most carefully

All law imposes compulsion A form of compulsory health insurance for those who cannot pay for voluntary insurance can be devised, adequately safeguarded, without involving what has been termed "socialized medicine"

Another conservative feature of this bill (S 1320) is its provision for medical education and research. If the people, through their Government, are spending money on medical care, promotion of medical education and research seems highly desirable as a means of maintaining standards and improving the effectiveness of that care In setting aside for education and research 2 per cent of the sums expended on medical care this safeguard seems satisfactorily provided

But just as with the problem of financing medical education, some doctors will have none of this In objecting they have gone to rather extraordinary extremes For example the National Physicians Committee, which is endorsed by the American Medical Association and whose endorsement is now before the Massachusetts Medical Society, spent some \$600,000 last year on propaganda from which the following is taken

THE MOST DEADLY MENACE

Over a period of ten years, no issue in the United States has held the deadly menace that is inherent in the relentless drive to impose on the American people — COMPULSORY HEALTH INSURANCE No other issue has been as assiduously and as persistently promoted by its sponsors

It has taken ten years to unmask the forces behind the sponsorship and to force the issue into the open NOW the sponsors have been unmasked The issue is in the open

The source of the unremitting and relentless drive for Compulsory Health Insurance — Socialized Medicine — is the Political Distribution of Medical Care in this country — is the Moscow dominated Communist Party of the United States

This program did not originate in the United States, but in the secret councils of world communism

The campaign for socialized medicine in the United States stems directly from Kremlin communism

Five years ago similar leaflets of this committee said that the forces behind the sponsorship were Nazism and Hitlerian totalitarianism But apparently that was a mistake However, there appears to be no mistake about Lloyd George, Roose-

affected, whereas in the other family the diagnosis was made in 4 male siblings

CASE REPORT

CASE 1 J W, a 22-year-old Negro, was admitted on January 27, 1947, to the Veterans Administration Hospital, Kecoughtan, Virginia, complaining of constant dull chest pain of 2 months' duration. Concomitant symptoms included exertional dyspnea, occasional hemoptysis and epistaxis. He also complained of weakness, weight loss and fatigue. About 2 weeks prior to admission he had become aware of a diminution of vision and bilateral swelling of the upper eyelids and of the parotid regions. Vague abdominal symptoms became manifest on the week of entry.

The past history was noncontributory. His father was said to have had carcinoma of the stomach.

Physical examination disclosed a well developed and well nourished, ambulant man, who was slightly dyspneic. There were several small, freely movable, nontender, hard nodules palpable in both upper eyelids. The lacrimal glands were enlarged. The mucosa of each nasal passage was hyperemic and excoriated, showing evidence of recent hemorrhages. In the lower portion of the right nasal passage near the vestibule there was a nodule, 2 mm in diameter, that appeared friable. The heart and lungs were essentially normal. There was marked voluntary-muscle spasm and moderate tenderness to palpation in the right upper quadrant. The liver, spleen and kidneys were not palpable. There were no other significant findings.

A roentgenogram of the chest showed a marked degree of symmetrical mottling extending from both hilar regions to the pulmonary periphery. The skull, bones of the hands and wrists showed normal architecture and density. A roentgenogram taken 2 weeks later showed a slight progression in the pulmonary lesion. A gastrointestinal series was normal. An electrocardiogram was within normal limits.

A complete blood count was entirely normal. The urine had a specific gravity of 1.020 and contained a trace of albumin, and an occasional white blood cell was seen in the centrifuged specimen. The blood Wassermann and Kahn tests were negative. The serum protein was 6.3 gm per 100 cc, with 2.7 gm of albumin and 3.6 gm of globulin. The nonprotein nitrogen was 35 mg per 100 cc. A sedimentation rate of 16 mm per hour (Cutler method) was present. The prothrombin time was 21 seconds. Repeated examinations of the sputum for acid-fast bacilli were negative.

The patient was treated with a modified tuberculin regimen consisting primarily of rest and a highly nutritious diet. Because of frequent nosebleeds the nodule in the right nasal passage was removed. There was no return of the epistaxis after this procedure. Microscopical examination revealed one large tubercle composed of epithelioid cells with no caseation or surrounding reaction. The diagnosis was Boeck's sarcoid.

After 2 months of hospitalization he developed a left facial-muscle paralysis which persisted for 4 weeks. The fundi showed bilateral papilledema. A spinal puncture showed normal fluid under a slight increase in pressure. The temperature ranged between 97° and 101°F. An intolerance to salicylates was observed in the course of treatment. There was no regression in the physical findings. However, after sufficient symptomatic improvement, he was discharged after four months in the hospital.

Seven weeks later he returned to the hospital because of an exacerbation of symptoms. He stated that a paralysis of the right side of the face had developed in the interim and that he now suffered almost constant headaches. He had also become aware of some difficulty in speaking.

Physical examination disclosed a dejected and emaciated man with stertorous breathing who constantly expectorated sputum consisting of saliva and streaks of blood. The nodules previously noted on the eyelids persisted. There was mild choking of both disks on funduscopic examination. Auditory perception in the left ear was impaired. The tongue protruded to the right, and a right facial-muscle paralysis was present. Below the angle of the right side of the jaw there were several small, movable, nontender nodules in the subcutaneous tissue. The epitrochlear lymph nodes were enlarged.

The temperature ranged from 97° to 100.2°F and was characterized by an afternoon rise.

A roentgenogram of the lung fields remained unchanged. A film of the sinuses revealed a polyp in the right antrum. An intravenous pyelogram and a barium enema were negative.

The red-cell count and hemoglobin were normal. The white-cell count was 7000, with 60 per cent neutrophils, 36 per cent lymphocytes, 1 per cent monocytes and 3 per cent eosinophils. The sedimentation rate was 20 mm per hour. A urinalysis showed a specific gravity of 1.015 and a trace of albumin. A few white cells and hyaline casts were seen in the sediment. The serum protein totaled 6.6 gm per 100 cc., the serum phosphorus was 3.2 mg, and the alkaline phosphatase 6.6 mg per 100 cc. The serum cholesterol was 264 mg, the blood sugar 87 mg, and the nonprotein nitrogen 30 mg per 100 cc. A urine concentration test showed that the kidneys were unable to concentrate higher than 1.015. Phenolsulfonephthalein kidney-function tests showed 20 to 50 per cent excretion of the dye in 1 hour. First-strength tuberculin — puri-

FIGURE 1 Photomicrograph of Biopsy Specimen in Case 1

fied protein derivative (0.00002 mg) — was negative, whereas second-strength (0.005 mg) was borderline positive.

A specimen for biopsy was taken from an epitrochlear lymph node. Microscopical section showed the node to be composed of nearly confluent tubercles demonstrating epithelioid proliferation with no surrounding reaction, no caseation and no giant cells (Fig 1). The diagnosis was Boeck's sarcoid.

CASE 2 E W, identical twin of J W, entered the Veterans Administration Hospital, Kecoughtan, Virginia, on August 25, 1947, because of a condyloma at the anal orifice.

The past history disclosed that in July, 1945, while in the European Theater of Occupation, the patient had begun to suffer from painful joints, fever and pruritus. He was sent to Ashburn General Hospital, Texas, where lumps appeared in various locations on the body. Weakness, weight loss, cough and periumbilical pains came into prominence. The lacrimal and parotid glands became enlarged. Shortly thereafter a

profession's discouragement of divergent opinion within the profession is unfortunate. Respect in a democracy for minority opinion is perhaps the most conservative way to contribute to the wisdom of majority opinion. Possibly it is this lack of considered debate by the profession that has resulted in its having no constructive program. Again, to quote Dr Park

Granted that it is impossible now to think through the problem of medical care to the very end, it is certainly possible to think a considerable way into it, some requirements are common to any comprehensive medical care plan, and are as evident now as twenty years away. There is no planning in what is going on, and this is because there is no medical leadership.

Its much touted "ten-point program" is no program in any original, dynamic, or constructive sense, or, indeed in any sense, but only a series of pious platitudes.

Its primary concern throughout as judged by its behavior has seemed to me to be aimed consistently at the preservation of the medical care system as it exists today at all costs. Disturbed, it cries out in the words of Fafnir coiled around his treasure, when the youthful Siegfried, the personification of the new order, approaches with his magic sword, "Lass mich schlafen."

In this critical period of change, when the handwriting appears on so many walls, the behavior of organized medicine is humiliating, and its leadership has seemed incredibly stupid.

As a member of the medical profession and the American Medical Association I regret that such criticism can justly be made. It is a serious in-

dictment of the profession. I am often shocked to learn how many physicians have so little information about the matters we are discussing other than what they obtain from the one-sided presentations of the National Physicians Committee and other organizations supporting that point of view. The constructive participation of the medical profession in the development of any national health program is essential for the accomplishment of a good job. Without more adequately financing medical education, research and care a good job cannot be done.

My purpose in speaking tonight is to stress that something is going to be done as remarked by Mr Baruch because of the public's demand, and to urge you as members of the Suffolk District Medical and Massachusetts Medical societies to give considered thought to these matters so that a good job may be done. If not, we as doctors will suffer, as well as the public. I mention specifically this society and the Massachusetts Medical Society not as a politically expedient way of ending comments that may be interpreted by some as unduly critical, but because the past history of both societies amply justifies the expectation that considered thought by you will result in much needed tolerant discussion, intelligent decisions and constructive action.

SARCOIDOSIS IN IDENTICAL TWINS*

JOSEPH F. SHERER, JR., M.D.,† AND ROBERT T. KELLEY, M.D.‡

LITTLE COMPTON, RHODE ISLAND, AND WASHINGTON, D. C.

SINCE the original descriptions by Besnier, Boeck and Schaumann of the disease that now bears their names, many papers¹⁻⁴ have adequately presented the characteristic clinical and pathological findings. However, relatively few authors have reported on the occurrence of sarcoidosis in siblings. No report has been made of sarcoidosis in twins.

Leitner⁵ mentions several authors who have described sarcoidosis as it occurred among members of the same family. He states that Richter found sarcoidosis in sisters. The older one showed involvement of the skin, typical lung findings and splenomegaly, the younger sister had cystic changes in the bones and lesions of the fingers. Dressler observed sarcoidosis in a sister and brother⁶ and in two brothers.⁷ The diagnosis was established on the basis of the clinical picture and roentgenologic findings. MacCormac⁸ described Boeck's sarcoid in sisters aged fifty-four and sixty-one years. In the younger the diagnosis was confirmed by biopsy

as well as typical skin lesions, the appearance of the lungs by roentgenography and a negative Mantoux test. The other sister showed similar lupoid patches, but further studies had not been performed. Bergmann⁹ reports the disease in 2 sisters, with death occurring in each case as a result of right-sided heart failure and chronic hematogenous tuberculosis. In 1 case an autopsy was performed. The other sister was thought to have had the same illness, owing to the strong similarity of the clinical course. Skin lesions of Boeck's sarcoid were seen in both cases. Seller and Berger¹⁰ observed sarcoidosis in 5 siblings in a family of 7, the diagnosis being established by biopsy. Boggild's¹¹ report consists of the findings in sisters, two and five years of age, with roentgenographic evidence of lesions in the bones of the hands that was considered pathognomonic of Boeck's sarcoid. There was no histologic evidence of the condition on biopsy.

The first to report sarcoidosis in siblings in the American literature were Robinson and Hahn.¹² They found Boeck's sarcoid in siblings of two unrelated families. In one family two brothers were

VITAMIN E IN THE TREATMENT OF ANGINA PECTORIS*

IVER S RAVIN, M D ,¹ AND KERMIT H KATZ, M D ‡

BOSTON

DURING the past two years, interest in the use of vitamin E in the treatment of various forms of heart disease has been aroused by several reports of its efficacy appearing in medical and nonmedical publications. In June, 1946, a magazine with nationwide circulation reported "a startling scientific discovery"

A treatment for heart disease which so far has succeeded against all common forms of the ailment. Large concentrated doses of vitamin E benefited four types of heart ailment: arteriosclerotic, hypertensive, rheumatic and coronary heart disease. The vitamin helps a failing heart. It eliminates anginal pain.¹

This publication aroused great interest among patients and physicians alike, for many it represented the first suggestion that vitamin E was therapeutically effective in heart disease. Later in the same month an editorial in the *Journal of the American Medical Association* urged the need for careful evaluation of any such report.²

Although vitamin E has been under investigation for many years and considerable knowledge has been accumulated regarding its chemical and physical properties,³ little is known about its function. All green plants have demonstrable amounts of the vitamin; it is practically impossible to produce an experimental deficiency in animals if natural foods are present in the diet. Deficiency diets have produced many different types of changes depending upon which animals are used. No studies have been made on human beings.

One of the most striking effects of experimental vitamin E deficiency is the occurrence of muscular dystrophy. Houchin and Smith⁴ noted that many of their rabbits on such diets died suddenly in circulatory collapse, manifesting cardiac dilatation on x-ray study before death. The degree of dystrophy was not sufficient, they believed, to have caused the deaths, which they attributed to cardiac failure. Gullickson and Calverley⁵ were also impressed by the phenomenon of sudden circulatory collapse, and were able to demonstrate electrocardiographic changes of a significant degree in 2 experiments on cattle that died in this manner on diets deficient in vitamin E. Post-mortem examination revealed atrophy and scarring of the heart muscle with an increase in cellular elements, some

resembling Aschoff bodies. However, Evans⁶ has shown that, in rats dying of muscular dystrophy, electrocardiographic studies were normal, and there were no demonstrable changes in the heart muscle. Mason and Telford⁷ maintained monkeys for years on a diet deficient in vitamin E. Although at death the skeletal muscles and the smooth muscles of the blood vessels, stomach, intestines, gall bladder and bronchi showed hypertrophic changes, there was little or no change in the cardiac muscle. Houchin and Smith⁴ have postulated that functional change can occur in heart muscle before anatomic change. They have demonstrated in cardiac muscle strips markedly abnormal oxygen uptake curves although no structural changes were perceptible. These authors have shown that the hearts of rabbits deficient in vitamin E are more sensitive to posterior pituitary extract than normal hearts. They have further shown that such rabbits have a much greater tolerance for digitalis glycosides than normal animals. They believe that deficiency of vitamin E leads to increased oxygen demand and decreased capacity for work. This is independent of heart volume, and occurs even in isolated strips of cardiac muscle. The reduced capacity for work leads to dilatation and a further increase in the oxygen requirement. Govier⁸ has investigated the relation of alpha-tocopherols to enzyme systems involved in intracellular oxidation, and believes that chronic anoxia may produce a relative vitamin E deficiency in the cell, which might result in damage to heart-muscle metabolism. It is also Mason's³ opinion that vitamin E is involved in intracellular oxidation.

The difficulty of applying these experimental and theoretical considerations to clinical disorders in man is apparent. It is not possible to demonstrate a constant cardiac lesion, the action of the vitamin is not thoroughly understood, and it is extremely unlikely that vitamin E deficiency exists, even in human beings whose diets are far below the usual requirements. Because it is not possible, therefore, to demonstrate vitamin E deficiency as an etiologic factor in heart disease, its use in human beings must be considered largely empirical.

In 1945, Vogelsang, Shute and Shute⁹ observed in a patient with thrombocytic purpura hemorrhagica, whom they were treating with large doses of vitamin E, coincidental improvement of angina pectoris. Subsequently, vitamin E was used in a variety of diseases of the heart, with uniformly satisfactory results. Shute and Vogelsang¹⁰ described marked improvement in an unselected series of 84 consecutive patients, all with anginal attacks as

*From the Department of Medicine, Boston University School of Medicine, and the Fifth and Sixth (Boston University) Medical Services, Boston City Hospital.

‡Assistant professor of medicine, Boston University School of Medicine, assistant director, Fifth and Sixth (Boston University) Medical Services, Boston City Hospital.

paralysis of the right side of the face developed. There was a loss of sense of smell and impairment of hearing on the right. Two biopsies at this hospital were reported diagnostic of Boeck's sarcoid. Over the following 20 months the patient gradually improved and was able to carry on his usual occupation.

Physical examination revealed a well developed and well nourished man. The weight was 134 pounds. On the right side of the face there appeared several small, verrucous vegetations. There was a large, round, firm mass anterior to and beneath each ear, with no adherence to the deeper structures. Small movable, nontender lymph nodes were felt along the posterior border of both sternocleidomastoid muscles. The sense of smell was lost. Enlarged epitrochlear and inguinal lymph nodes were palpable, and shotty nodes were felt in both axillae. Beneath the glans penis were several verrucous excrescences. Small papular lesions, 1 or 2 cm in diameter, were present over both tibial crests. A large cauliflower-like

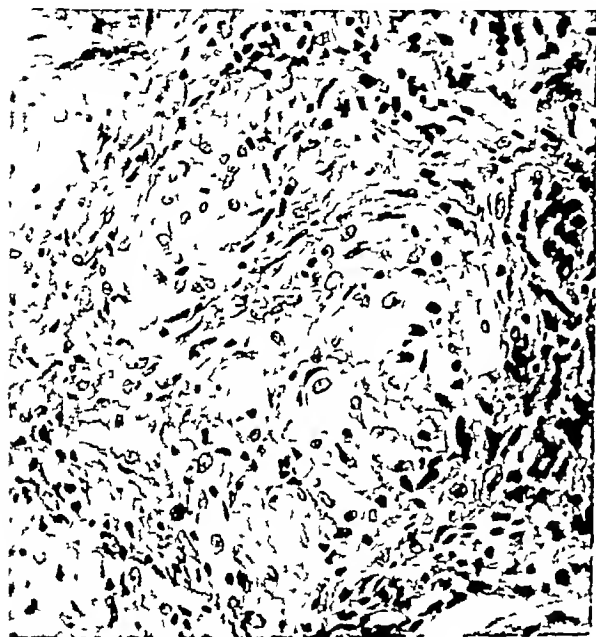

FIGURE 2 Photomicrograph of Biopsy Specimen in Case 2

mass, about 10 cm in its longest diameter, was attached to a pedicle outside the anal mucosa.

A roentgenogram of the chest disclosed the hilar lymph nodes to be moderately enlarged. There was diffuse nodular infiltration extending from the hilar regions into the parenchyma of both lungs. Roentgenograms of the hands, feet and all the long bones of the extremities were normal.

The blood picture was normal. The serum calcium was 11 mg, the phosphorus was 3.6 mg, and the alkaline phosphatase 6.6 mg per 100 cc. The serum protein was 6.6 gm per 100 cc, with 3.6 gm of albumin and 3.0 gm of globulin. The serum cholesterol was 223 gm per 100 cc. The urine concentrated to 1:020. A phenolsulfonephthalein test showed 35 per cent excretion of the dye in 1 hour. No Bence-Jones protein was found.

First-strength and second-strength tuberculin (purified protein derivatives) were negative. An electrocardiogram was normal. A specimen of a lesion on the skin was taken for biopsy. On microscopical examination there were subcutaneous tubercles with no reaction caseation or Langhans's cells (Fig. 2). The diagnosis was Boeck's sarcoid.

DISCUSSION

Little has been written regarding the role played by the constitution in sarcoidosis. Dressler,⁶ com-

menting on his finding of sarcoidosis in siblings, expressed the opinion that the constitution had a significant effect on the pathogenesis of this disease, which he believed was tuberculous in origin. In his first case report he noted that the sister and brother affected with the disease bore a stronger resemblance to each other than to other siblings of the family. This suggests a constitutional predisposition.

Bergmann⁹ also believed that sarcoidosis is a benign atypical form of tuberculosis. He considered the disease to be manifested by a reaction in the form of a generalized hyaline sclerosis on a constitutional basis. He further stated that this form of reaction is in a stage of mutation as a consequence of widespread infection of the general population. One of his points in favor of a constitutional background is the appearance of the disease in siblings. He showed in his report that his patients had other likenesses, such as obesity, that are at times considered to have a constitutional basis.

Robinson and Hahn¹² mentioned the striking similarity in the symptoms and clinical course of the disease in 2 brothers.

In the cases presented above we were impressed by the unusual similarity of the clinical picture of a disease of such protean manifestations. This observation, together with the fact that the patients were identical twins, further indicates a constitutional basis for this disease.

SUMMARY

Two cases of sarcoidosis in identical twins are reported.

The role of the constitutional factor in sarcoidosis is discussed. It is concluded that the constitution may play a significant part in the pathogenesis.

VITAMIN E IN THE TREATMENT OF ANGINA PECTORIS*

IVER S RAVIN, M D,† AND KERMIT H KATZ, M D ‡

BOSTON

DURING the past two years, interest in the use of vitamin E in the treatment of various forms of heart disease has been aroused by several reports of its efficacy appearing in medical and nonmedical publications. In June, 1946, a magazine with nationwide circulation reported "a startling scientific discovery"

A treatment for heart disease which so far has succeeded against all common forms of the ailment. Large concentrated doses of vitamin E benefited four types of heart ailment: arteriosclerotic, hypertensive, rheumatic and coronary heart disease. The vitamin helps a failing heart. It eliminates anginal pain.¹

This publication aroused great interest among patients and physicians alike, for many it represented the first suggestion that vitamin E was therapeutically effective in heart disease. Later in the same month an editorial in the *Journal of the American Medical Association* urged the need for careful evaluation of any such report.²

Although vitamin E has been under investigation for many years and considerable knowledge has been accumulated regarding its chemical and physical properties,³ little is known about its function. All green plants have demonstrable amounts of the vitamin; it is practically impossible to produce an experimental deficiency in animals if natural foods are present in the diet. Deficiency diets have produced many different types of changes depending upon which animals are used. No studies have been made on human beings.

One of the most striking effects of experimental vitamin E deficiency is the occurrence of muscular dystrophy. Houchin and Smith⁴ noted that many of their rabbits on such diets died suddenly in circulatory collapse, manifesting cardiac dilatation on x-ray study before death. The degree of dystrophy was not sufficient, they believed, to have caused the deaths, which they attributed to cardiac failure. Gullickson and Calverley⁵ were also impressed by the phenomenon of sudden circulatory collapse, and were able to demonstrate electrocardiographic changes of a significant degree in 2 experiments on cattle that died in this manner on diets deficient in vitamin E. Post-mortem examination revealed atrophy and scarring of the heart muscle with an increase in cellular elements, some

resembling Aschoff bodies. However, Evans⁶ has shown that, in rats dying of muscular dystrophy, electrocardiographic studies were normal, and there were no demonstrable changes in the heart muscle. Mason and Telford⁷ maintained monkeys for years on a diet deficient in vitamin E. Although at death the skeletal muscles and the smooth muscles of the blood vessels, stomach, intestines, gall bladder and bronchi showed hypertrophic changes, there was little or no change in the cardiac muscle. Houchin and Smith⁴ have postulated that functional change can occur in heart muscle before anatomic change. They have demonstrated in cardiac muscle strips markedly abnormal oxygen uptake curves although no structural changes were perceptible. These authors have shown that the hearts of rabbits deficient in vitamin E are more sensitive to posterior pituitary extract than normal hearts. They have further shown that such rabbits have a much greater tolerance for digitalis glycosides than normal animals. They believe that deficiency of vitamin E leads to increased oxygen demand and decreased capacity for work. This is independent of heart volume, and occurs even in isolated strips of cardiac muscle. The reduced capacity for work leads to dilatation and a further increase in the oxygen requirement. Govier⁸ has investigated the relation of alpha tocopherols to enzyme systems involved in intracellular oxidation, and believes that chronic anoxia may produce a relative vitamin E deficiency in the cell, which might result in damage to heart-muscle metabolism. It is also Mason's³ opinion that vitamin E is involved in intracellular oxidation.

The difficulty of applying these experimental and theoretical considerations to clinical disorders in man is apparent. It is not possible to demonstrate a constant cardiac lesion, the action of the vitamin is not thoroughly understood, and it is extremely unlikely that vitamin E deficiency exists, even in human beings whose diets are far below the usual requirements. Because it is not possible, therefore, to demonstrate vitamin E deficiency as an etiologic factor in heart disease, its use in human beings must be considered largely empirical.

In 1945, Vogelsang, Shute and Shute⁹ observed in a patient with thrombocytic purpura hemorrhagica, whom they were treating with large doses of vitamin E, coincidental improvement of angina pectoris. Subsequently, vitamin E was used in a variety of diseases of the heart, with uniformly satisfactory results. Shute and Vogelsang¹⁰ described marked improvement in an unselected series of 84 consecutive patients, all with anginal attacks as

paralysis of the right side of the face developed. There was a loss of sense of smell and impairment of hearing on the right. Two biopsies at this hospital were reported diagnostic of Boeck's sarcoid. Over the following 20 months the patient gradually improved and was able to carry on his usual occupation.

Physical examination revealed a well developed and well nourished man. The weight was 134 pounds. On the right side of the face there appeared several small, verrucous vegetations. There was a large, round, firm mass anterior to and beneath each ear, with no adherence to the deeper structures. Small movable, nontender lymph nodes were felt along the posterior border of both sternocleidomastoid muscles. The sense of smell was lost. Enlarged epitrochlear and inguinal lymph nodes were palpable, and shotty nodes were felt in both axillae. Beneath the glans penis were several verrucous excrescences. Small papular lesions, 1 or 2 cm in diameter, were present over both tibial crests. A large cauliflower-like

FIGURE 2 Photomicrograph of Biopsy Specimen in Case 2

mass, about 10 cm in its longest diameter, was attached to a pedicle outside the anal mucosa.

A roentgenogram of the chest disclosed the hilar lymph nodes to be moderately enlarged. There was diffuse nodular infiltration extending from the hilar regions into the parenchyma of both lungs. Roentgenograms of the hands, feet and all the long bones of the extremities were normal.

The blood picture was normal. The serum calcium was 11 mg, the phosphorus was 3.6 mg, and the alkaline phosphatase 6.6 mg per 100 cc. The serum protein was 6.6 gm per 100 cc, with 3.6 gm of albumin and 3.0 gm of globulin. The serum cholesterol was 223 gm per 100 cc. The urine concentrated to 1020. A phenolsulfonephthalein test showed 35 per cent excretion of the dye in 1 hour. No Bence-Jones protein was found.

First-strength and second-strength tuberculin (purified protein derivatives) were negative. An electrocardiogram was normal. A specimen of a lesion on the skin was taken for biopsy. On microscopical examination there were subcutaneous tubercles with no reaction caseation or Langhans' cells (Fig. 2). The diagnosis was Boeck's sarcoid.

DISCUSSION

Little has been written regarding the role played by the constitution in sarcoidosis. Dressler,⁶ com-

menting on his finding of sarcoidosis in siblings, expressed the opinion that the constitution had a significant effect on the pathogenesis of this disease, which he believed was tuberculous in origin. In his first case report he noted that the sister and brother affected with the disease bore a stronger resemblance to each other than to other siblings of the family. This suggests a constitutional predisposition.

Bergmann⁹ also believed that sarcoidosis is a benign atypical form of tuberculosis. He considered the disease to be manifested by a reaction in the form of a generalized hyaline sclerosis on a constitutional basis. He further stated that this form of reaction is in a stage of mutation as a consequence of widespread infection of the general population. One of his points in favor of a constitutional background is the appearance of the disease in siblings. He showed in his report that his patients had other likenesses, such as obesity, that are at times considered to have a constitutional basis.

Robinson and Hahn¹² mentioned the striking similarity in the symptoms and clinical course of the disease in 2 brothers.

In the cases presented above we were impressed by the unusual similarity of the clinical picture of a disease of such protean manifestations. This observation, together with the fact that the patients were identical twins, further indicates a constitutional basis for this disease.

SUMMARY

Two cases of sarcoidosis in identical twins are reported.

The role of the constitutional factor in sarcoidosis is discussed. It is concluded that the constitution may play a significant part in the pathogenesis.

and rales at both lung bases. No toxicity was evident from the combined use of digitalis and vitamin E.

DISCUSSION

Vitamin E is a mixture of alpha, beta and gamma tocopherols. These may be present in varying proportions. It is claimed that the alpha tocopherol content of vitamin E determines its efficacy in the treatment of heart disease.¹⁰ In no case has it been maintained that the heart disease represented

uniform benefit in as short a period as a few days to a few weeks.

SUMMARY

A small, carefully selected group of patients suffering from angina pectoris were treated with 500 mg of vitamin E (approximately 250 mg of alpha tocopherol) daily. These patients were studied by an exercise-tolerance test, and note was made of any subjective or objective change during the course of treatment, which varied from four to twenty-four

either vitamin E or alpha tocopherol deficiency. Rather, it must be assumed that these substances exert a positive action comparable to other, non-vitamin, drugs in increasing the efficiency of the circulation. For this purpose, it is maintained that doses much larger than those that might otherwise be used are necessary for beneficial results. The alpha tocopherol content of the preparation used in this study was 50 per cent, making the daily dosage 250 mg of alpha tocopherol. This is comparable to the average dosage of the various preparations originally used by the Shutes and their co-workers in their treatment of patients suffering from angina pectoris. The method of assay of the alpha tocopherol content of vitamin E has been criticized by these workers, who maintain that biologic assay is the only reliable procedure. These points remain to be proved conclusively. At present they represent items of possible controversy in attempting to reconcile the results of the present study with those of others who have reported almost

weeks. In only 1 case was there even slight objective benefit.

a major symptom. Many etiologic types were involved, and all degrees of functional impairment were represented. Eighty-one improved on this therapy, in 52 cases the improvement was noted to be complete or marked. In this series the vitamin E was administered in various forms — in some cases as mixed tocopherols, and in others as alpha tocopherol. Shute states that any capsule containing 50 mg of natural mixed tocopherols has been crudely equated to 25 mg of alpha tocopherol. He has recently observed that the average satis-

tocopherols. Assay of this product has shown it to have an alpha tocopherol content of 50 per cent — which brought the daily dosage of alpha tocopherol to 250 mg. During the course of the investigation, patients were required to avoid the use of mineral oil or cod liver oil, as well as any iron preparations, which Shute believes may inactivate the vitamin.

Table 1 presents the results of the administration of the tocopherols to this group. Eleven patients were accepted for treatment. The etiology of their heart disease was arteriosclerosis or hypertension,

factory dose is between 200 and 300 mg of alpha tocopherol.¹¹

The present study represents an attempt to evaluate vitamin E therapy on a small, carefully controlled group of patients with angina pectoris as the presenting complaint. The method of evaluation was similar to that described by Riseman and Stern¹² for testing the efficacy of various drugs in angina pectoris by an exercise-tolerance test under controlled conditions. All patients were systematically investigated in the usual fashion with history, physical examination, routine blood counts, blood Hinton test, electrocardiogram and x-ray film of the heart. On three separate occasions, at weekly intervals, they were given the two-step test before being started on vitamin therapy. In this way a base line of performance was established, and the patients were familiarized with the procedure. Each patient was required to rest for an hour before the test, and no nitroglycerin was taken during this time. The patients were rechecked at intervals of two or three weeks after starting treatment, and the performance was recorded. Each patient kept a memorandum of the number of anginal attacks experienced between examinations, and of the number of nitroglycerin tablets used. After suitable control determinations had been made, each patient was given 250 mg of vitamin E, to be taken twice daily, in the form of natural mixed

or both, in 10 cases, and syphilis in 1. The duration of anginal symptoms varied from one to ten years. The duration of treatment ranged from four to twenty-four weeks, the average for the group being fourteen weeks. The columns headed "Before Treatment" represent the average of three two-step tests, and the number of nitroglycerin tablets used daily. The columns headed "After Treatment" represent the performance at the end of the testing period, and the number of nitroglycerin tablets taken at that time. Performances recorded during the testing period closely approximated the figures given for the end of treatment. Subjective changes reflected estimates by the patients of any improvement in feeling of well-being.

In no case except Case 2 was there any difference between the performance before and after treatment, and in this case the consumption of nitroglycerin had increased markedly in the month during which the patient was followed. The patient in Case 9 experienced slight subjective improvement, but there was no improvement in the performance of the two-step test. The patient in Case 3 had been taking digitalis for a year prior to vitamin E treatment. It was necessary to continue this, whether or not she was taking the vitamin. When, for a three-week period she was unable to purchase digitalis and omitted its use, she required redigitalization because of the development of severe dyspnea.

and rales at both lung bases. No toxicity was evident from the combined use of digitalis and vitamin E.

DISCUSSION

Vitamin E is a mixture of alpha, beta and gamma tocopherols. These may be present in varying proportions. It is claimed that the alpha tocopherol content of vitamin E determines its efficacy in the treatment of heart disease.¹⁰ In no case has it been maintained that the heart disease represented

uniform benefit in as short a period as a few days to a few weeks.

SUMMARY

A small, carefully selected group of patients suffering from angina pectoris were treated with 500 mg of vitamin E (approximately 250 mg of alpha tocopherol) daily. These patients were studied by an exercise-tolerance test, and note was made of any subjective or objective change during the course of treatment, which varied from four to twenty-four

TABLE 1 (Continued)

CASE No	TWO-STEP TEST				NITROGLYCERIN TABLETS		DURATION OF TREATMENT	SUBJECTIVE CHANGE	OBJECTIVE CHANGE
	BEFORE TREATMENT		AFTER TREATMENT		BEFORE TREATMENT	AFTER TREATMENT			
	trips	min	trips	min	per day	per day	wk		
1	32	5	30	5	7-10	7-10	4	None	None
2	12	2	16	2	20-30	30-40	4	Slight improvement	None

either vitamin E or alpha tocopherol deficiency. Rather, it must be assumed that these substances exert a positive action comparable to other, non-vitamin, drugs in increasing the efficiency of the circulation. For this purpose, it is maintained that doses much larger than those that might otherwise be used are necessary for beneficial results. The alpha tocopherol content of the preparation used in this study was 50 per cent, making the daily dosage 250 mg of alpha tocopherol. This is comparable to the average dosage of the various preparations originally used by the Shutes and their co-workers in their treatment of patients suffering from angina pectoris. The method of assay of the alpha tocopherol content of vitamin E has been criticized by these workers, who maintain that biologic assay is the only reliable procedure. These points remain to be proved conclusively. At present they represent items of possible controversy in attempting to reconcile the results of the present study with those of others who have reported almost

weeks. In only 1 case was there even slight objective benefit.

MONORCHISM*

A Report of Two Cases

GEORGE K. KAWAICHI, M D,† PHILIP COOPER, M D,‡ AND HAROLD F. O'DONNELL, M D§

WICHITA, KANSAS

CONGENITAL absence of one testis or both testes is still considered rare. Since the advent of surgical treatment for "cryptorchidism," however, an increasing number of cases of monorchism or anorchism have been reported. Gruber,¹ in 1878, reviewed the literature for a period of three hundred years and was able to verify only 23 cases of monorchism and 7 cases of anorchism. In the more recent literature, Thorek and Thorek² reported, in 1933, a case of monorchism. Rea,³ in 1938, reviewed the literature and found 40 reported cases of anorchism or monorchism. Of these, 11 were bilateral, and 29 unilateral. He added 6 cases of his own. In 1940, Counseller, Nichols and Smith⁴ reported 7 cases of monorchism. The absence occurred on the left side in 4 and on the right in 3 cases. This brought the number of reported cases of congenital absence of the testes, in the available literature, to 47 cases, 11 being bilateral and 36 unilateral. Because of the importance of bearing in mind that a significant proportion of "cryptorchidism" may actually represent cases of testicular absence and in view of the need of a uniform approach to the problem of monorchism or anorchism, the following cases are presented.

CASE REPORTS

CASE 1. H F S., a 20-year-old man, was admitted to the hospital on April 27, 1949, with a history of an undescended left testis since birth. The patient was admitted by his private physician to have the condition investigated because of the possibility of development of a malignant lesion in an undescended testis.

Physical examination revealed an old, healed right inguinal herniorrhaphy scar. There was a normal testis on the right in proper position. No testis was palpable on the left, but there was a fullness at the left external inguinal ring, suggestive of a testis. Rectal examination revealed a normal prostate. Examinations of the blood and urine were essentially negative. The blood Kahn test was also negative.

On May 3, the left inguinal canal was exposed through the usual herniorrhaphy incision. The spermatic-cord elements, including the vas deferens, were found leading into the scrotum. However, no testis was observed either in the scrotum or the inguinal canal. The cord was followed down to the scrotum, where it ended in a fine ligament. At the end of the vas deferens was a small, soft elongated mass, about 1 cm in length and 3 mm in width. This was excised to the level of the internal inguinal ring. A small indirect hernial sac was found. This was opened, and the peritoneal cavity in this region was inspected and palpated, there was no evidence of a testis. The incision in the skin and muscle was extended, and a meticulous dissection was then made in the

retroperitoneal region as far as the lower pole of the left kidney, but no testis was found. A herniorrhaphy was completed, and the wound closed in the usual manner.

Microscopical sections of the tissues removed from the scrotum revealed atrophic epididymis, in which no spermatozoa were seen, and vas deferens, but no testicular tissue.

CASE 2. C J H., a 29-year-old man, was admitted to the hospital on August 16, 1948, with the diagnosis of a right undescended testis since birth.

Physical examination revealed the left testis to be normal in size and position. The right testis could not be palpated. Rectal examination revealed a normal prostate, and no abnormal masses were palpable. Examinations of the blood and urine, as well as the blood Kahn test, were negative.

On August 23, at exploration through a right inguinal incision, the spermatic cord was found in the usual position leading down into the scrotum, and ending in a ligamentous structure. The vas deferens ended in a few strands of soft tissue, and tissue somewhat suggestive of atrophic epididymis, but no testicular tissue was found. The cord with the attached tissues was removed at the internal inguinal ring. A herniorrhaphy was then done, and the wound closed. The peritoneal cavity was then opened through a right rectus incision, and a careful search was made for an undescended testis. The parietal peritoneum was also incised lateral to the ascending colon and the retroperitoneal area thoroughly searched, but no testis was found. The parietal peritoneum was sutured. A long, chronically inflamed appendix was easily delivered and removed.

Microscopical study of the removed tissue revealed an atrophic vas deferens but no definite epididymis or testicular tissue.

DISCUSSION

Anorchism and monorchism should not be confused with cryptorchidism or with a testis showing clinical evidence of atrophy. Anorchism refers to the absence of both testes and monorchism to the absence of one testis.

The testis develops embryologically from the genital fold, which is essentially part of the mesonephros. The epididymis and the vas deferens develop from elements of the mesonephros. The epididymis and the testis form luminal continuity approximately at the 60-mm stage. One can readily see from this brief review that the close anatomic relation of the epididymis and the testis during development make the possibility of the descent of the epididymis into the scrotum and the retention of the testis in the abdomen very unlikely.

Conceivably, there may be slight separation of the testis from the epididymis and vas deferens. This has been demonstrated by Badenoch,⁵ who reported 3 cases of complete separation of the epididymis and the testis in a series of 42 patients operated upon for cryptorchidism. In the first case, the testis was just below the internal inguinal ring, and the epididymis was found near the external inguinal

*From the Veterans Administration Hospital. Published with permission of the Chief Medical Director, Department of Medicine and Surgery, Veterans Administration, who assumes no responsibility for opinions expressed or conclusions drawn by the authors.

†Urologist, Veterans Administration Hospital.

‡Chief of surgery, Veterans Administration Hospital.

§Consultant in urology, Veterans Administration Hospital.

ring In the second case, the testis was intra-abdominal but near the internal inguinal ring, and the epididymis was found in the upper part of the scrotum In the last case, the testis was just below the external inguinal ring, and the epididymis was at the bottom of the scrotum

Counseller, Nichols and Smith⁴ also point out that if other parts of the seminal apparatus can be readily located, the presence of a gonad in a remotely aberrant position is unlikely

Lazarus and Marks⁶ reported a case of complete separation of the epididymis and vas deferens and an abdominal testis The epididymis and vas were found in the inguinal canal, and the testicle was found just inside the internal inguinal ring

According to Felix,⁷ an abdominal testis, if present, will be found in the region of the internal inguinal ring

Bremer and Farber⁸ offer the following opinion concerning the absence of a testis with evidence of vas and epididymis in the scrotum

If sections have been taken of the "vas and atrophic epididymis" and the tissues identified as such microscopically, the best possibility in explaining the absent testicle is that primary atrophy of the testis occurred, either during development or later after descent into the scrotum Due to the close anatomic relationships of the epididymis and testis during development, the possibility of their separation with retention of the testis in the canal and descent of the epididymis and vas is very unlikely

This opinion, in conjunction with other reported findings, we believe establishes a logical surgical approach to the problem of anorchism or monorchism

There is some difference of opinion among surgeons regarding what constitutes adequate exploration for an apparent absent testis Some advise

merely exploration of the inguinal canal and scrotum, others advise additional exploration of the retroperitoneal structures It must be admitted that a meticulous retroperitoneal operative dissection may fail to disclose a minute remnant of testicular tissue, but it should reveal a testis of any reasonable size

CONCLUSION

On the basis of this review, it is believed that in the presence of vas deferens, and epididymis in the scrotum, exploration for the testis could be safely limited to exploration of the scrotum, inguinal canal and the peritoneal cavity in the region of the internal inguinal ring

The problem arises whether such a limited procedure can be justified in the presence only of a vas deferens in the scrotum In all probability it is justified, but the absolute justification must await more clinical observations

In the 2 cases reported, primary atrophy of the testis in one and primary atrophy of the testis and epididymis in the other are the most logical explanations for their absence at the time of surgical exploration

MONORCHISM*

A Report of Two Cases

GEORGE K. KAWAICHI, M.D.,† PHILIP COOPER, M.D.,‡ AND HAROLD F. O'DONNELL, M.D.§

WICHITA, KANSAS

CONGENITAL absence of one testis or both testes is still considered rare. Since the advent of surgical treatment for "cryptorchidism," however, an increasing number of cases of monorchism or anorchism have been reported. Gruber,¹ in 1878, reviewed the literature for a period of three hundred years and was able to verify only 23 cases of monorchism and 7 cases of anorchism. In the more recent literature, Thorek and Thorek² reported, in 1933, a case of monorchism. Rea,³ in 1938, reviewed the literature and found 40 reported cases of anorchism or monorchism. Of these, 11 were bilateral, and 29 unilateral. He added 6 cases of his own. In 1940, Counseller, Nichols and Smith⁴ reported 7 cases of monorchism. The absence occurred on the left side in 4 and on the right in 3 cases. This brought the number of reported cases of congenital absence of the testes, in the available literature, to 47 cases, 11 being bilateral and 36 unilateral. Because of the importance of bearing in mind that a significant proportion of "cryptorchidism" may actually represent cases of testicular absence and in view of the need of a uniform approach to the problem of monorchism or anorchism, the following cases are presented.

CASE REPORTS

CASE 1 H. F. S., a 20-year-old man, was admitted to the hospital on April 27, 1949, with a history of an undescended left testis since birth. The patient was admitted by his private physician to have the condition investigated because of the possibility of development of a malignant lesion in an undescended testis.

Physical examination revealed an old, healed right inguinal herniorrhaphy scar. There was a normal testis on the right in proper position. No testis was palpable on the left, but there was a fullness at the left external inguinal ring, suggestive of a testis. Rectal examination revealed a normal prostate. Examinations of the blood and urine were essentially negative. The blood Kahn test was also negative.

On May 3, the left inguinal canal was exposed through the usual herniorrhaphy incision. The spermatic-cord elements, including the vas deferens, were found leading into the scrotum. However, no testis was observed either in the scrotum or the inguinal canal. The cord was followed down to the scrotum, where it ended in a fine ligament. At the end of the vas deferens was a small, soft elongated mass, about 1 cm in length and 3 mm in width. This was excised to the level of the internal inguinal ring. A small indirect hernial sac was found. This was opened, and the peritoneal cavity in this region was inspected and palpated; there was no evidence of a testis. The incision in the skin and muscle was extended, and a meticulous dissection was then made in the

retroperitoneal region as far as the lower pole of the left kidney, but no testis was found. A herniorrhaphy was completed, and the wound closed in the usual manner.

Microscopical sections of the tissues removed from the scrotum revealed atrophic epididymis, in which no spermatozoa were seen, and vas deferens, but no testicular tissue.

CASE 2 C. J. H., a 29-year-old man, was admitted to the hospital on August 16, 1948, with the diagnosis of a right undescended testis since birth.

Physical examination revealed the left testis to be normal in size and position. The right testis could not be palpated. Rectal examination revealed a normal prostate, and no abnormal masses were palpable. Examinations of the blood and urine, as well as the blood Kahn test, were negative.

On August 23, at exploration through a right inguinal incision, the spermatic cord was found in the usual position leading down into the scrotum, and ending in a ligamentous structure. The vas deferens ended in a few strands of soft tissue, and tissue somewhat suggestive of atrophic epididymis, but no testicular tissue was found. The cord with the attached tissues was removed at the internal inguinal ring. A herniorrhaphy was then done, and the wound closed. The peritoneal cavity was then opened through a right rectus incision, and a careful search was made for an undescended testis. The parietal peritoneum was also incised lateral to the ascending colon and the retroperitoneal area thoroughly searched, but no testis was found. The parietal peritoneum was sutured. A long, chronically inflamed appendix was easily delivered and removed.

Microscopical study of the removed tissue revealed an atrophic vas deferens but no definite epididymis or testicular tissue.

DISCUSSION

Anorchism and monorchism should not be confused with cryptorchidism or with a testis showing clinical evidence of atrophy. Anorchism refers to the absence of both testes and monorchism to the absence of one testis.

The testis develops embryologically from the genital fold, which is essentially part of the mesonephros. The epididymis and the vas deferens develop from elements of the mesonephros. The epididymis and the testis form luminal continuity approximately at the 60-mm stage. MONORCHISM*

A Report of Two Cases

GEORGE K. KAWAICHI, M.D.,† PHILIP COOPER, M.D.,‡ AND HAROLD F. O'DONNELL, M.D.§

WICHITA, KANSAS

CONGENITAL absence of one testis or both testes is still considered rare. Since the advent of surgical treatment for "cryptorchidism," however, an increasing number of cases of monorchism or anorchism have been reported. Gruber,¹ in 1878, reviewed the literature for a period of three hundred years and was able to verify only 23 cases of monorchism and 7 cases of anorchism. In the more recent literature, Thorek and Thorek² reported, in 1933, a case of monorchism. Rea,³ in 1938, reviewed the literature and found 40 reported cases of anorchism or monorchism. Of these, 11 were bilateral, and 29 unilateral. He added 6 cases of his own. In 1940, Counseller, Nichols and Smith⁴ reported 7 cases of monorchism. The absence occurred on the left side in 4 and on the right in 3 cases. This brought the number of reported cases of congenital absence of the testes, in the available literature, to 47 cases, 11 being bilateral and 36 unilateral. Because of the importance of bearing in mind that a significant proportion of "cryptorchidism" may actually represent cases of testicular absence and in view of the need of a uniform approach to the problem of monorchism or anorchism, the following cases are presented.

CASE REPORTS

CASE 1. H. F. S., a 20-year-old man, was admitted to the hospital on April 27, 1949, with a history of an undescended left testis since birth. The patient was admitted by his private physician to have the condition investigated because of the possibility of development of a malignant lesion in an undescended testis.

Physical examination revealed an old, healed right inguinal herniorrhaphy scar. There was a normal testis on the right in proper position. No testis was palpable on the left, but there was a fullness at the left external inguinal ring, suggestive of a testis. Rectal examination revealed a normal prostate. Examinations of the blood and urine were essentially negative. The blood Kahn test was also negative.

On May 3, the left inguinal canal was exposed through the usual herniorrhaphy incision. The spermatic-cord elements, including the vas deferens, were found leading into the scrotum. However, no testis was observed either in the scrotum or the inguinal canal. The cord was followed down to the scrotum, where it ended in a fine ligament. At the end of the vas deferens was a small, soft elongated mass, about 1 cm in length and 3 mm in width. This was excised to the level of the internal inguinal ring. A small indirect hernial sac was found. This was opened, and the peritoneal cavity in this region was inspected and palpated; there was no evidence of a testis. The incision in the skin and muscle was extended, and a meticulous dissection was then made in the

retroperitoneal region as far as the lower pole of the left kidney, but no testis was found. A herniorrhaphy was completed, and the wound closed in the usual manner.

Microscopical sections of the tissues removed from the scrotum revealed atrophic epididymis, in which no spermatozoa were seen, and vas deferens, but no testicular tissue.

CASE 2. C. J. H., a 29-year-old man, was admitted to the hospital on August 16, 1948, with the diagnosis of a right undescended testis since birth.

Physical examination revealed the left testis to be normal in size and position. The right testis could not be palpated. Rectal examination revealed a normal prostate, and no abnormal masses were palpable. Examinations of the blood and urine, as well as the blood Kahn test, were negative.

On August 23, at exploration through a right inguinal incision, the spermatic cord was found in the usual position leading down into the scrotum, and ending in a ligamentous structure. The vas deferens ended in a few strands of soft tissue, and tissue somewhat suggestive of atrophic epididymis, but no testicular tissue was found. The cord with the attached tissues was removed at the internal inguinal ring. A herniorrhaphy was then done, and the wound closed. The peritoneal cavity was then opened through a right rectus incision, and a careful search was made for an undescended testis. The parietal peritoneum was also incised lateral to the ascending colon and the retroperitoneal area thoroughly searched, but no testis was found. The parietal peritoneum was sutured. A long, chronically inflamed appendix was easily delivered and removed.

Microscopical study of the removed tissue revealed an atrophic vas deferens but no definite epididymis or testicular tissue.

DISCUSSION

Anorchism and monorchism should not be confused with cryptorchidism or with a testis showing clinical evidence of atrophy. Anorchism refers to the absence of both testes and monorchism to the absence of one testis.

The testis develops embryologically from the genital fold, which is essentially part of the mesonephros. The epididymis and the vas deferens develop from elements of the mesonephros. The epididymis and the testis form luminal continuity approximately at the 60-mm stage. One can readily see from this brief review that the close anatomic relation of the epididymis and the testis during development make the possibility of the descent of the epididymis into the scrotum and the retention of the testis in the abdomen very unlikely.

Conceivably, there may be slight separation of the testis from the epididymis and vas deferens. This has been demonstrated by Badenoch,⁵ who reported 3 cases of complete separation of the epididymis and the testis in a series of 42 patients operated upon for cryptorchidism. In the first case, the testis was just below the internal inguinal ring, and the epididymis was found near the external inguinal

tion of BAL make it difficult to determine how much credit to give the drug for recovery

Holman⁷⁷ reports on the use of trichophytin in thromboangitis obliterans. Ninety-three per cent of these patients had clinical trichophytosis compared with only 73 per cent of the control patients. Four times as many patients with this disease had positive trichophytin tests as the controls did. This paper suggests a more thorough trial of trichophytin in cases of thromboangitis obliterans.

Treatment may be quite simple if based on careful study of the disease. Block⁷⁸ states that the best results in trench foot can be obtained if patients are induced to walk as early as possible. He made histologic studies of the skin of 15 soldiers suffering from chronic trench foot and found little difference from the biopsy specimens of 8 healthy controls.

INFECTION

Dodd et al.⁷⁹ report 88 cases of aphthous stomatitis in children up to fourteen years of age. The type of stomatitis described is a definite clinical entity with the virus of herpes simplex as the causative factor. It is probable that the disease represents a primary herpetic infection.

Burnet and Williams⁸⁰ also conclude that aphthous stomatitis in infants is the primary herpetic infection. They believe that once infection has begun the virus of herpes simplex remains in the body for life, showing activity under a suitable stimulus such as fever or trauma. The article states that in childhood a nonspecific resistance to the primary infection develops. When this stage is reached, the population is permanently divided into two groups—herpetic and nonherpetic. In the former, the virus persists, occasionally manifesting itself by lesions and by supplying a constant or intermittent antigen stimulus to maintain antibodies at high level. The nonherpetic patient is exposed but, owing to development of resistance, goes unscathed. In conclusion Burnet and Williams state that the herpes virus is probably the only virus that lives an almost symbiotic existence in man. Herpes simplex can be a very annoying and disfiguring affliction when it recurs frequently. It may appear monthly in highly susceptible persons.

Nagler⁸¹ summarizes his article on herpes simplex by stating that when a heated inactivated preparation of herpes simplex virus is inoculated intracutaneously in herpetic persons, a specific erythematous reaction is produced. A positive intracutaneous reaction is regularly correlated with the presence of circulating antibodies against herpes virus. In a later article he⁸² states that a herpes simplex skin-test reagent prepared from infected amniotic fluids has been shown to be easier to prepare, to contain only a trace of nonspecific protein and to give more specific results than a chorioallantoic reagent previously used.

Leff⁸³ reports a forty-four-year-old patient with herpes zoster of the right side of the chest and the Ramsay-Hunt syndrome—left-facial-muscle paralysis, decreased pain sensation over the left side of the face in all three divisions, absent left corneal reflex, loss of taste over two thirds of the left side of the tongue, moderate deafness of the left ear, vesicular eruption on the left anterior faucial pillar and decreased sensation in the left external auditory canal. These clinical findings confirm the current opinion that the Ramsay-Hunt syndrome is not geniculate ganglionitis alone but rather a concurrent involvement of several cranial nerves.

According to Mandelbaum and Hollander,⁸⁴ the diagnosis of Brill's disease (American typhus fever) may be established by biopsy. They find that rickettsial diseases produce vasculitis and perivasculitis. Rickettsias may also be found in the biopsy specimen. The dependability of the biopsy in diagnosis must be confirmed.

Reporting on Kaposi's varicelliform eruption, Unger⁸⁵ states that the disease has been proved to be herpes simplex superimposed on a previous skin disease. In 1944 Brunsting and Barton reported 67 cases, 79 per cent having had atopic dermatitis.

In a comprehensive review of Kaposi's varicelliform eruption, Ruchman⁸⁶ reports 4 cases. He states that of 96 reported cases, 75 were in children. The death rate was 23 per cent in infants and 9 per cent in adults, this is probably higher than the average, for milder cases were probably not reported frequently. Three adults and 1 child (fourteen months old) are discussed in Ruchman's paper. All had an atopic background and had been exposed to herpes simplex for periods of five to ten days, and none to vaccinia. One patient died of respiratory failure after leukopenia developed with fever and disorientation.

Allison and Hobbs⁸⁷ state that "epidemic strains" of *Staphylococcus pyogenes* are usually responsible for pemphigus neonatorum, which is frequently accompanied by staphylococcal conjunctivitis. The most probable course of infection is via the nose and hands of the nurse to the infant's skin, but infants' bath and towels may be important links. Prevention of infection probably depends on exclusion of heavy nasal or skin carriers of *Staphylococcus pyogenes* from the nursery and observation of meticulous preventive measures in the nursery. When all hospitals exclude the use of mercury compounds as preventives against impetigo of the newborn and for antiseptic measures, the incidence of dermatitis and diarrhea among these infants will be much less.

Two American soldiers from the same community in the United States who were tattooed on the same day by the same operator in Melbourne, Australia, developed tuberculoid leprosy in these areas about two and a half years later. One patient

DERMATOLOGY (Concluded)

JOHN G. DOWNING, M.D.*

BOSTON

BLOOD

Mycosis fungoides fortunately is a comparatively rare disease. Hence, there are a limited number of cases in the various reports on therapy. Henstell⁶⁸ reports that, irrespective of the stage, 6 cases responded immediately to nitrogen mustard. All were radioresistant. Cases with a prolonged premycotic stage showed the best response. In my opinion most follow-up examinations have shown that the improvement has been temporary.

Law⁶⁹ states that tumor formation in mice with transplanted leukemia responded favorably to urethane.

In a paper on the treatment of neoplastic disease with nitrogen mustard, Taffel⁷⁰ reports the results of 16 cases (6 cases of Hodgkin's disease, 2 of stem-cell lymphoma, and 1 each of eight other neoplastic diseases). Six doses of 0.1 mg per kilogram of body weight was given daily, later this was reduced to four doses, and in some cases to 0.05 mg per kilogram. Four patients, 2 of whom had Hodgkin's disease, were given two courses of treatment, so that twenty courses were given in all. No one of the patients was cured, and 10 died (treatment was given within the last three years). The 6 patients still living are far from cured. Although Hodgkin's disease seemed most susceptible to the drug, there was not enough improvement to delay death appreciably. One case of mycosis fungoides was substantially improved, thus far for five months. Taffel comments that the drug is toxic, depresses blood elements and may cause alarming agranulocytic leukopenia and thrombocytopenia. He concludes that in his clinic radiotherapy is preferred for these diseases if the disease is localized, nitrogen mustard is reserved for patients with diffuse systemic involvement and those who have become resistant to x-ray therapy.

Pincoffs⁷¹ summarizes the therapeutic use of nitrogen mustard. He states that reports of 150 cases of different authors treating Hodgkin's disease, lymphosarcoma, chronic leukemia, polycythemia vera, multiple myeloma and a few other neoplasms indicate that nitrogen mustard deserves a subsidiary position in the treatment of the first two diseases and possibly some cases of chronic leukemia. Pincoffs states that more investigation is indicated. He believes that irradiation, as long as it is effective, is the treatment of choice.

Green⁷² treated 2 cases of mycosis fungoides with thorium X, 2000 units in isopropyl alcohol. It was

painted on small affected areas of the skin weekly for six weeks. Erythema and itching were relieved after the first application, but recurred in a few weeks. Subsequently, 100 units of thorium X in saline solution was given intravenously weekly for twelve weeks, with some relief. The blood showed no change after the injections. Again, the local areas were treated with twelve weekly paintings. Four weeks after the last application, the painted areas showed marked decrease or absence of erythema, and the itching was completely relieved. The tumor and ulcer when painted also showed definite improvement.

A six-year clinical evaluation of internal radiation therapy with radioactive phosphorus (P³²) is given by Doon et al.,⁷³ who state that this isotope has the greatest value in polycythemia vera. It is a valuable adjunct in chronic leukemias that are intolerant or resistant to roentgen radiation, but has frequently accentuated the acute leukemias. It has failed to control Hodgkin's disease and may threaten the integrity of the bone marrow. Deep bone pain from metastatic cancers may be relieved, but it is doubtful if metastases are retarded. Pruritus in these cases has been controlled at times. Multiple myeloma, mycosis fungoides, metastases to bone and exfoliating dermatitides were not basically improved.

In a report on the effect of rutin on the permeability of cutaneous capillaries, Ambrose and DeEds⁷⁴ state that previous experiments showed rutin (vitamin P) to have no protective action against capillary fragility. Capillary permeability is determined by the injection of trypan blue intravenously, followed by irritation of the skin with chloroform or histamine. Rutin was injected intravenously in 22 rabbits that were irritated by chloroform. In doses of 100 to 200 mg per kilogram of body weight it decreased capillary permeability under the conditions of this test.

Colloidal gold containing the radioactive isotope Au 198 has been suggested for the treatment of diseases of the lymphoid system. In view of the dermatitis-producing factor of gold, this drug should be used carefully when there is a cutaneous manifestation.⁷⁵

Holley⁷⁶ reports 12 cases of agranulocytosis following intensive arsenotherapy treated with BAL. After discontinuance of the arsenic, BAL was given, in conjunction with considerable therapy, such as transfusions and penicillin. The early treatment of these cases with intensive supportive therapy, the inconclusive diagnoses and the early administra-

*Professor of dermatology and syphilology Tufts College Medical School professor of dermatology Boston University School of Medicine

tion of BAL make it difficult to determine how much credit to give the drug for recovery

Holman⁷⁷ reports on the use of trichophytin in thromboangitis obliterans. Ninety-three per cent of these patients had clinical trichophytosis compared with only 73 per cent of the control patients. Four times as many patients with this disease had positive trichophytin tests as the controls did. This paper suggests a more thorough trial of trichophytin in cases of thromboangitis obliterans.

Treatment may be quite simple if based on careful study of the disease. Block⁷⁸ states that the best results in trench foot can be obtained if patients are induced to walk as early as possible. He made histologic studies of the skin of 15 soldiers suffering from chronic trench foot and found little difference from the biopsy specimens of 8 healthy controls.

INFECTION

Dodd et al.⁷⁹ report 88 cases of aphthous stomatitis in children up to fourteen years of age. The type of stomatitis described is a definite clinical entity with the virus of herpes simplex as the causative factor. It is probable that the disease represents a primary herpetic infection.

Burnet and Williams⁸⁰ also conclude that aphthous stomatitis in infants is the primary herpetic infection. They believe that once infection has begun the virus of herpes simplex remains in the body for life, showing activity under a suitable stimulus such as fever or trauma. The article states that in childhood a nonspecific resistance to the primary infection develops. When this stage is reached, the population is permanently divided into two groups—herpetic and nonherpetic. In the former, the virus persists, occasionally manifesting itself by lesions and by supplying a constant or intermittent antigen stimulus to maintain antibodies at high level. The nonherpetic patient is exposed but, owing to development of resistance, goes unscathed. In conclusion Burnet and Williams state that the herpes virus is probably the only virus that lives an almost symbiotic existence in man. Herpes simplex can be a very annoying and disfiguring affliction when it recurs frequently. It may appear monthly in highly susceptible persons.

Nagler⁸¹ summarizes his article on herpes simplex by stating that when a heated inactivated preparation of herpes simplex virus is inoculated intracutaneously in herpetic persons, a specific erythematous reaction is produced. A positive intracutaneous reaction is regularly correlated with the presence of circulating antibodies against herpes virus. In a later article he⁸² states that a herpes simplex skin-test reagent prepared from infected amniotic fluids has been shown to be easier to prepare, to contain only a trace of nonspecific protein and to give more specific results than a chorioallantoic reagent previously used.

Leff⁸³ reports a forty-four-year-old patient with herpes zoster of the right side of the chest and the Ramsay-Hunt syndrome—left-facial-muscle paralysis, decreased pain sensation over the left side of the face in all three divisions, absent left corneal reflex, loss of taste over two thirds of the left side of the tongue, moderate deafness of the left ear, vesicular eruption on the left anterior faucial pillar and decreased sensation in the left external auditory canal. These clinical findings confirm the current opinion that the Ramsay-Hunt syndrome is not geniculate ganglionitis alone but rather a concurrent involvement of several cranial nerves.

According to Mandelbaum and Hollander,⁸⁴ the diagnosis of Brill's disease (American typhus fever) may be established by biopsy. They find that rickettsial diseases produce vasculitis and perivasculitis. Rickettsias may also be found in the biopsy specimen. The dependability of the biopsy in diagnosis must be confirmed.

Reporting on Kaposi's varicelliform eruption, Unger⁸⁵ states that the disease has been proved to be herpes simplex superimposed on a previous skin disease. In 1944 Brunsting and Barton reported 67 cases, 79 per cent having had atopic dermatitis.

In a comprehensive review of Kaposi's varicelliform eruption, Ruchman⁸⁶ reports 4 cases. He states that of 96 reported cases, 75 were in children. The death rate was 23 per cent in infants and 9 per cent in adults, this is probably higher than the average, for milder cases were probably not reported frequently. Three adults and 1 child (fourteen months old) are discussed in Ruchman's paper. All had an atopic background and had been exposed to herpes simplex for periods of five to ten days, and none to vaccinia. One patient died of respiratory failure after leukopenia developed with fever and disorientation.

Allison and Hobbs⁸⁷ state that "epidemic strains" of *Staphylococcus pyogenes* are usually responsible for pemphigus neonatorum, which is frequently accompanied by staphylococcal conjunctivitis. The most probable course of infection is via the nose and hands of the nurse to the infant's skin, but infants' bath and towels may be important links. Prevention of infection probably depends on exclusion of heavy nasal or skin carriers of *Staphylococcus pyogenes* from the nursery and observation of meticulous preventive measures in the nursery. When all hospitals exclude the use of mercury compounds as preventives against impetigo of the newborn and for antiseptic measures, the incidence of dermatitis and diarrhea among these infants will be much less.

Two American soldiers from the same community in the United States who were tattooed on the same day by the same operator in Melbourne, Australia, developed tuberculoid leprosy in these areas about two and a half years later. One patient

had multiple tattoos elsewhere, but these areas produced no leprosy.⁸⁸

Dunham et al.⁸⁹ isolated from a patient with Reiter's disease a filtrable agent that was pathogenic for mice.

Church and Mason⁹⁰ report 10 cases of cutaneous diphtheria occurring in American soldiers in Germany during an epidemic. The diagnosis was made by culture. In 3 cases the foot and leg, in the same number the hands or arm, and in 2 the lower abdomen and the genitalia were involved.

Cutaneous diphtheria simulating lymphopathia venereum and ectodermosis erosiva plurionificalis has been described by Reiss.⁹¹

Miller and his associates⁹² report the following types of cutaneous and mucomembranous lesions in histoplasmosis: ulceration and granulomas—oval, small, discrete, gray-domed nodules, papules, plaques and punched-out ulcers, purpuric lesions, abscesses, furunculosis and impetiginized areas on the scalp, chest and back and generalized, and dermatitis, local or generalized. They present a comprehensive study and report a case of histoplasmosis in a thirty-seven-year-old laborer who six years previously had received x-ray therapy for what was diagnosed Hodgkin's disease. This is a complete consideration of the subject, with an interesting discussion of the possible relation to reticuloendothelial neoplasms. The discussion showed that many cases were being seen but not reported.

Histoplasmosis is apparently more readily recognized, owing to the copious literature. Martz⁹³ reports the case of a three-year-old girl who was malnourished. She had contracted pertussis a year previously, followed by an unexplained fever and loss of weight. Later symptoms were diarrhea, bleeding lips, gums and fingernails, ecchymosis and lymphadenopathy. An excised lymph node showed histoplasmosis. The patient was hospitalized, but died five days later. Autopsy showed the intestinal tract with its lymph nodes to be particularly involved and harboring numerous histoplasma organisms. This disease is usually found predominantly in the gastrointestinal tract or the respiratory organs, and it is believed that this suggests the mode of entry. The histoplasmin skin test is not dependable as a diagnostic measure.

In an article on histoplasmin and tuberculin reactions in university freshmen, Prior and Allen⁹⁴ report histoplasmin in 75.8 per cent in the southwestern part of the country, as compared to 16.8 per cent in the northeastern section. They found no similar geographic difference existing for tuberculin reactors. Histoplasmosis is probably related to the soil, possibly in the way that coccidioides is related to it.

Disseminated ulcerating sporotrichosis with visceral involvement occurred in a sixty-seven-year-old man. There was painful swelling in the knee,

followed six weeks later by a generalized papular eruption without fever. Biopsy showed a tuberculoid reaction, the lymph nodes were normal. The patient's condition was generally good for five weeks after the appearance of the papules, but he suddenly became worse and died in five days. Autopsy showed *Sporotrichum schenckii* in the skin lesions, spleen, liver, bones and so forth.⁹⁵

The common contaminant, aspergillus, is usually saprophytic, but may be pathogenic under certain conditions. Cawley⁹⁶ reports a fatal case in a child seven and a half years of age. Post-mortem examination showed multiple abscesses in various organs. *Aspergillus fumigatus* was cultured from all lesions.

Baer and Muskatblat⁹⁷ report the case of a twenty-four-year-old man with an eruption on the palms and soles since birth, and on the body and extremities since the age of fourteen. It was diagnosed as erythroderma ichthiosiforme congenitale, but scrapings from the hands, feet, thighs, abdomen, chest and back showed positive cultures for *Trichophyton purpureum*, and the patient was treated accordingly. As stated above, generalized fungous infections may occur in persons with congenital cutaneous dystrophy. The terrain is ideal for fungous growth.

Suppurative ringworm contracted from cattle is reported by Fowle and Georg.⁹⁸ Clinically, it consisted of deep suppurative lesions of the bearded area, kerion lesions of the bearded area and scalp and agminate folliculitis of the glabrous skin.

Wolf⁹⁹ states that at least fifty-three different species of fungi have been reported in the literature as causative of otomycosis. Some were known pathogens, others were not. Most of these fungi are nonpathogens and usually associated with bacteria, and it is not known which is responsible for the otitis. Many so-called cases of otomycosis are merely a seborrheal dermatitis with secondary invasion of nonpathogenic fungi, or pseudomonas organisms.

A case of mucormycosis of the central nervous system associated with hemochromatosis is reported by LeCompte and Meissner.¹⁰⁰ The diagnosis was made from autopsy sections (not cultured).

Sheldon and Heyman¹⁰¹ present histologic studies of 8 cases of lymphogranuloma venereum proved by isolation and identification of the virus. The picture of all three lesions is identical, consisting chiefly of perivascular large mononuclear infiltration, which with some plasma cells and few giant cells obliterates some swollen blood vessels, producing necrosis, polymorphonuclear leukocytes then invade and produce abscesses. The authors believe that the histologic picture is sufficiently distinct to warrant biopsy as a diagnostic procedure in suspected lymphogranuloma venereum.

Glass¹⁰² reports that the hairs and spores from tinea capitis due to *M. audouinii* and *M. lanosum*

are infectious up to one year in 85 per cent and 10 per cent of the cases, respectively

Neves and Costa¹⁰³ define tinea nigra as a contagious, inoculable and autoinoculable dermatomycosis caused by *Cladosporium mansonii* and *C. werneckii*. The clinical characteristics are black or brown pigmentation on the trunk, neck and palms

Muskatblit¹⁰⁴ states that in primary actinomycosis of the skin the probable portal of entry in his case was a carious left lower molar. Normal persons may have pathogenic actinomycetes that are carried by the lymphatics in and around carious teeth. Penicillin is more rapidly effective than the sulfonamides

Two cases of chromoblastomycosis in Panama, diagnosed by sclerotic cells on direct culture of scabs or agglutination, are reported by Calero¹⁰⁵. A good result was obtained in one case with 1200 r filtered through 2 mm of copper and 1 mm of aluminum. In the other case electrocautery was followed by 1000 r

Bernhardt¹⁰⁶ reports dermatophytosis of the face caused by *T. camerounense*. It was the first isolation in America and the first from a human lesion. The patient was seen at the Skin Clinic of the Boston City Hospital

Inflammatory plaques on the lower legs are a common complication of dermatophytosis according to Waisman¹⁰⁷. They are thought to be caused by lymphatic transmission of hemolytic streptococci through fissures on the soles. The question is raised whether they might not be due to fungus toxins. Such cases are uncommon

Muskatblit¹⁰⁸ reports the case of a woman with an itchy eruption on the left foot of four months' duration, this was followed by an eruption on both hands. Scrapings from the fingers were negative, and those from the left sole positive. Cultures showed two colonies: one of these was *T. interdigitale*, white, downy with irregular folds, grooves and convolution, the other was identified as *T. rubrum*, an elevated center with a pinkish down, a flat yellow and powdery middle zone and a peripheral fringe of submerged rays, powdery on the surface and deep red on transillumination

In a report of primary onychomycosis due to aspergillus, Bereston and Waring¹⁰⁹ cultured many colonies of *Aspergillus flavus* and no other fungi. The nail had a dull-green color

Michelson¹¹⁰ treated 6 cases of cutaneous tuberculosis (2 with lupus vulgaris, 1 with tuberculosis colliquativa and 3 with erythema induratum) with viosterol in oil, 150,000 units, and a quart of milk daily. Under treatment for two to five months, all cases were improved, though none were cured

Sagher and Miterstein¹¹¹ report 6 cases of leprosy of the anterior portion of the eyeball treated with Grenz rays. Relief from pain and arrest of the leprosy process were noted in the majority of cases

However, 1 case seemed adversely affected by the radiation

In 1942 herpes simplex (febrilis) was cured within a few days by the internal administration of gynergen (4 to 6 mg of ergotamine tartrate daily) and daily local application of gynergen solutions. Excellent results have been obtained for the neuralgic symptoms of herpes zoster, with disappearance of cutaneous lesions, with daily intravenous injections of gynergen in 0.5-cc doses. Improvement was noted after the third or fourth injection, and medication was then discontinued¹¹². The danger of vascular accidents after the use of ergot or its compounds caused the discontinuance of this drug in dermatology over forty years ago

Three cases of anthrax responded to penicillin therapy, and the patients recovered without incident¹¹³

DDT in various combinations has been recommended for parasitic diseases, including scabies. Various proprietary preparations are warmly advocated^{114, 115}

Hexamidine (a new antiseptic) in 1:1000 hydroalcoholic solution was used in impetigo and the pyodermas, with cure in three to five days without the addition of antiseptic ointments¹¹⁶

According to Cormia and Alsever¹¹⁷ penicillin is a valuable adjunct in pyoderma, but it should not be used without a prior sensitivity test. It is best given in a water-soluble ointment base following hot boric acid packs and opening of the pustules. A concentration of 500 units per gram of ointment is adequate when the causative organisms are sensitive to penicillin. When they are sensitive to penicillin, but only in greater concentrations, the amount of penicillin in the ointment must be increased. Supplementary therapy with sulfonamides has been of limited value

Dermacid, consisting of 6 per cent of sulfacetamide (albuclid) in a vanishing-cream base, is recommended in the treatment of multiple septic sores and spots, impetigo, septic abrasions and folliculitis barbae¹¹⁸

Nascent iodine in the form of iodoform (after cleaning and drying of the lesion) or a 10 per cent solution of sodium iodate is suggested in the treatment of tropical ulcers¹¹⁹

When aspergillus extract was deprived of known bacteriostatic or antitoxic properties and injected subcutaneously in a man suffering from a staphylococcal infection, the lesions were decongested within twenty-four hours¹²⁰

In the treatment of carate (pinta), injections of 1,200,000 units of penicillin caused disappearance of the treponemas and the erythema on the arms of the patient¹²¹

Penicillin in peanut oil and beeswax is apparently the method of choice in the treatment of yaws¹²². At least 1,200,000 units is necessary for an adult, the dose being graded according to age. Ninety-

one per cent of those treated showed apparent cure or satisfactory progress.¹²³ Penicillin is apparently the ideal treatment for the early stages, subsequent prolonged arsenical treatment may be necessary in resistant infections.

Willcox et al.¹²⁴ report gold salts as a curative in 2 patients with Reiter's syndrome not associated with bacillary dysentery.

Antimony is recommended for the treatment of American cutaneous leishmaniasis.¹²⁵

Streptomycin was effective in 3 cases of granuloma inguinale reported by Barton and his associates.¹²⁶ The authors lamented the fact that they did not have available sufficient streptomycin to treat these cases sufficiently.

A Negro suffering from sporotrichosis was treated with iontophoresis, with a strong solution of iodine (USP) used in 1:100 dilution at the start and concentrated to 1:50 over a period of three months. Treatments were given for twenty to thirty minutes, five days a week. Improvement was noticed after two weeks' treatment and continued until a cure was obtained.¹²⁷

Iontophoresis with formaldehyde and copper sulfate has been found useful in the treatment of dermatophytosis and hyperhidrosis.¹²⁸ The danger of formaldehyde is its sensitizing properties.

A 1 per cent solution of zinc chloride is deemed unsatisfactory in superficial mycotic infections, except in crural dermatoses and in tinea glabrosa, in which its use seems promising. In this same report, Dolce and Nickerson¹²⁹ found proper foot hygiene and the wearing of sandals instead of "GI" shoes of value in relieving mycotic infections.

Kirby and McNaught¹³⁰ recommend that patients with actinomycosis due to the aerobic *Nocardia asteroides* (*Actinomyces asteroides*) be treated with sulfonamide compounds and penicillin as vigorously as those infected with the anaerobic *Actinomyces bovis* and also that surgical drainage, iodides and roentgen-ray therapy be used as indicated. Generally the aerobic *N. asteroides* responds to sulfonamides, and the anaerobic *A. bovis* responds to penicillin.

In a report on fungicidal and fungistatic properties in vitro of clavacin (a filtrate of *A. clavatus*) on dermatophytes the results varied with the pH of the filtrate, the potency of the filtrate and the time of contact between the test fungi and the filtrate. Organisms found susceptible were, in order of susceptibility *Epidermophyton floccosum*, *T. violaceum*, *M. audouinii*, *T. rubrum*, *M. lanosum* and *T. gypseum*.¹³¹

According to Hopkins,¹³² undecylenic acid and dinitro-cyclohexylphenol gave the highest percentage of clinical successes in dermatophytoses of the feet. The former was believed to be the best for subacute cases. Undecylenic acid, propionic acid and benzoic acid were the least irritating.

Muskatblit¹³³ reports undecylenic acid as a good fungicide, but no better than others. He found no irritation, even in the acute phases.

The claim is made that sodium caprylate ointment (10 per cent), having no sensitizing action and relieving irritation even in denuded areas, is excellent for dermatomycosis of the feet.¹³⁴

In a 400-man ground crew unit of the Royal Air Force in the Netherlands East Indies, the incidence of ringworm of the feet and body was dramatically reduced by a few simple prophylactic measures. Jolly¹³⁵ states that the men wore clean cotton underpants daily, used special, clean foot towels and wore wooden clogs, with a single canvas strap, at all times. A minimum amount of foot powder was used between the toes after drying the skin. The lesions on the body were treated with 1 per cent chrysarobin in Lassar's paste, and the facial lesions with Whitfield's ointment. Brilliant green (1:500 in alcohol) with 3 per cent salicylic acid was used between the toes. The incidence of new cases dropped from 41 at the beginning of the experiment to 2 or 3 a month by the end of the experimental period.

Undecylenic and propionic acids in the prevention and treatment of dermatophytosis are listed by Sulzberger and Kanof¹³⁶ in order of efficacy as follows: undecylenic acid — undecylenate powder, diodoquin — 5 per cent talc, vioform — 1 to 3 per cent in talc, calcium zinc propionate powder, sodium propionate powder, United States Navy foot powder, boric-salicylic acid powder, talcum powder, and thiourea, 5 per cent in talc.

Tinea capitis due to *M. audouinii* was treated with 10 per cent copper undecylenate or 5 per cent salicylanilic ointment or both.¹³⁷ Irradiation is still recommended as the treatment of choice in tinea capitis.¹³⁸ Considering the risk in the hands of most operators, this treatment should be performed only by a dermatologist, or roentgenologist, specially trained for this type of therapy.

A thorough consideration of the entire study of fatty acids (of sweat) as fungicides and fungistatics is reported by Peck and Russ.¹³⁹ Caprylic and propionic fatty acids (of sweat) were combined and their effect in vitro and vivo on fungi and fungous infections of the scalp, pubis, anus, nails, hands and feet was observed. This mixture was superior in vitro to other fatty acids of sweat, and appeared more effective than any other fatty acids tried for these diseases. The ideal fungicide and curative agent for fungous infections of the skin has not yet been discovered. The fatty acids are very promising, their chief advantage being that they are for the most part nonirritating and do not sensitize. As to their curative powers, there seems to be a discrepancy in the various reports of investigators.

Studying fungicides for vaginal moniliasis, Hessel-tine¹⁴⁰ found that the most promising were ricinoleic

acid and three forms of cetyl ammonium chloride, all of which were completely fungistatic

Kendall¹⁴¹ reports the treatment of monilial vulvovaginitis with tap-water douche followed by 2.5 per cent undecylenic acid and 10 per cent zinc undecylenate in a base of equal parts of vanishing cream and lubricating jelly (desenex ointment). It is a simple nonstaining treatment.

Glycerite of hydrogen peroxide acts on organisms resistant to penicillin. Its use in the treatment of otitis externa seems justified.¹⁴²

SCLEROSSES

Two interesting cases of periarteritis nodosa show the value of biopsies in diseases in which physical signs are too variable to establish a diagnosis. The first patient presented a quiescent pulmonary tuberculosis, but active tuberculous lymph nodes in the neck. With each attack of fever, nodules characteristic of periarteritis nodosa appeared, suggesting a tuberculous antigen as the etiologic factor for the skin nodules. The patient recovered. The other patient, with no history of sensitization or skin lesions, died within a year of periarteritis involving the abdominal organs, muscles, brain and kidneys.¹⁴³

In view of the tendency to attribute various common inflammatory reactions to anaphylaxis, the thorough work of Goddard¹⁴⁴ is of more than academic interest. Using sensitized guinea pigs he showed that granulomas resulting from anaphylaxis have more histiocytes and eosinophils, with giant cells, than inflammatory granulomas — that is, they are quantitatively and qualitatively different.

In an experiment with rutin, Raiman et al.¹⁴⁵ found that it protects guinea pigs against anaphylactic shock but not against histamine shock.

Wuerthele¹⁴⁶ reports a case of scleroderma treated with promin. A 5 per cent jelly was applied three times daily, and in three months the patient was able to return to work.

Presenting a case of sclerema adiposum neonatorum (proved by biopsy), Sternbach and Robinson¹⁴⁷ discuss the distinction between this disease, scleredema neonatorum and pseudosclerema (subcutaneous fat necrosis). Sixteen hours after birth the baby developed clonus of the facial and arm muscles, on the second day there was spasticity of all the extremities, cyanosis and regurgitation. Four days later there was thrush and a hard subcutaneous mass in the left arm, followed by a scalp infection with gangrenous slough over the occiput. Twelve days after birth there were many hard subcutaneous nodules over most of the body, and the patient died at sixty-four days. Autopsy showed a typical skin picture. The other organs were normal except for the liver, which showed cloudy swelling and hydropic degeneration.

Liebow and Feil¹⁴⁸ found that in lupus erythematosus disseminatus, electrocardiographic abnormalities were noted as long as ten months before death and that they became progressively more abnormal. This report shows the frequency with which the myocardium is attacked by lupus erythematosus.

Thirty cases of lupus erythematosus (chiefly the chronic discoid type) were treated by Schmidt¹⁴⁹ with nicotinic acid by mouth and gold intramuscularly and intravenously. The dosage for the nicotinic acid was 50 to 100 mg orally after meals. Smoking and other habits that might produce vasoconstriction were restricted. The dosage of gold sulfide is graduated from 2.0 to 5.0 cc every five days.

NEW GROWTHS

Woodburne¹⁵⁰ reports that synovial cysts, ganglions and the like were best treated with x-ray therapy — 150 KV 3 mm al., two doses of 500 r each in one week. Slight atrophy occurred with this treatment, but this according to the author may have to be accepted if symptoms warrant the treatment. In my opinion surgery produces better results.

From England comes the report of a rare disease, keratoderma punctata, by Phillips.¹⁵¹ The patient, a thirty-two-year-old man, gave a history of small hard lumps on the creases of the palms and inner borders of the feet, the symptoms having developed three months previously. The plugs remained about a week and dropped out, and new ones developed.

According to Drucker,¹⁵² the results of the treatment of 37 cases of hemangioendothelioma indicate that surgical excision and irradiation offer the best therapy. The etiology is indefinite, but the disease is often considered as being due to trauma, evolving from hemangioma to the malignant form hemangioendothelioma. Metastasis occurs through the blood stream and sometimes through the lymphatics, and tends to recur after surgery.

From Australia comes a report on a new method of treating capillary hemangiomas by tattoo with titanium or zinc oxide, with the occasional addition of mercury sulfide (red) or hydrated chrome oxide (green) to adjust the color. The tattoo material is deposited between the capillary bed and the basal-cell layer, thereby permitting the pigment of the latter to give its natural color to the skin. Seven patients thus treated were satisfied with the cosmetic result.¹⁵³

Miller et al.¹⁵⁴ present an article on the general consideration of leukoplakia of the vulva. One hundred and forty-three cases were studied, including the hypertrophic and the atrophic krauroses. Careful studies revealed no valuable etiologic findings. Although the authors offer no substitute for surgery, they appear rather too critical of it. They consider that surgical excision may have to be used for symptomatic relief, but vulvectomy is an imperfect sub-

stitute for a medical cure, which, it is hoped, some day will be available. However, they strongly advocate radical excision, including lymphadenectomy for patients with proved carcinomatous changes.

Thomson¹⁵⁵ reports a case of granulosus rubra nasi in a ten-year-old boy. The patient had a symmetrically red sweating nose (involving the tip and midline to the bridge), and the normal and family history was negative for a similar defect. Williams believes the term "granulosus" should be deleted, with "nevus" as a substitute.

The report of schwannoma of the face, a rare skin tumor, is given by Thumin.¹⁵⁶ The twenty-one-year-old patient presented a tumor of four months' duration in the nasolabial-fold region. It was encapsulated, soft, friable, lobulated and gray, and measured approximately 4.0 by 1.5 by 1.0 cm. Microscopically, the tumor was diagnosed as neurilemmoma.

Blank¹⁵⁷ reports that in 88 patients with plantar warts he obtained 95 per cent cures with a new method of treatment. The wart is pared, and 90 per cent phenol is applied precisely to its surface, fuming nitric acid is then applied, causing a sputter. A round pad is applied, and finally 60 per cent salicylic acid. Walking is recommended to extrude the verruca, and five days later the lesion is observed and retreated if necessary. This is rather strenuous treatment, all three chemicals can cause great destruction of tissue.

Complications following the bismuth injection of verrucae is reported by Cameron.¹⁵⁸ A digital wart was injected with a drop of bismuth sodium tartrate. Two days later there was painful swelling of the area, with fever and axillary tenderness on palpation, but no lymphangitis. Cameron considers the case a toxic reaction to the heavy metal and believes that the risk does not justify such treatment of an innocuous wart. The same reaction can occur from an infection.

Kile and Welsh¹⁵⁹ have attempted to revive liquid oxygen in dermatologic practice, treating verruca vulgaris, condyloma acuminata, hemangioma, leukoplakia, seborrheic keratoses, senile keratoses, granuloma pyogenicum and folliculitis keloidalis. They report satisfactory response, with a soft scar that has not been followed by a keloid, even in persons prone to keloid. Its use in chronic discoid lupus erythematosus has been encouraging. Liquid oxygen was discarded many years ago in favor of better methods of therapy.

Sullivan and Blanchard,¹⁶⁰ after studying the reason for the action of podophyllotoxin on warts, conclude that it is the probable active ingredient of podophyllin.

McLellan¹⁶¹ describes the accidental discovery of a new method of treating senile warts. A patient who was suffering from fractured ribs was strapped with adhesive. On removal of the adhesive a few weeks later the senile warts were also removed.

Low-Beer¹⁶² used radioactive phosphorus in the treatment of basal-cell carcinomas, warts and hemangiomas and found the results very satisfactory. Radioactive phosphorus of the measured amount was placed on blotting paper and applied to the lesion. It produces a beta radiation.

Eberhard¹⁶³ reports the results of treatment of 492 cases of epitheliomas with a total of 760 lesions. Treatment consisted of surgery with a cold knife (no cautery or electric knife), fractionated x-ray therapy or interstitial radium. The choice of treatment depended on the size and location of the lesion, as well as the cosmetic effect, and not on histology. Biopsy is advocated to make sure the lesion belongs in the epithelioma group. A three-year follow-up study showed 66 per cent of patients living and free of epithelioma, 18 per cent had died of other diseases. By statistical analysis the cure rate was 83.3 per cent, which according to Eberhard compares favorably with general results obtained by others. There was no statistically significant difference in the results obtained by the three methods of treatment. Discussing the paper, Ullmann claimed considerably higher cure rates.

The feature of chemosurgical treatment of facial cancer, according to Mohs,¹⁶⁴ is microscopical control, using zinc chloride fixative paste after keratin is made penetrable by dichloroacetic acid. Surgery is determined by the microscopical examination of the zinc chloride fixed tissue. Two hundred and thirty-two basal-cell and 103 squamous-cell cancers were treated, with 100 per cent and 84 per cent cures respectively. I fail to see any improvement over complete surgical excision, except when a cosmetic result is not important. Pictures of their results were excellent.

Considering the action of podophyllum on normal skin, condylomata acuminata and verrucae vulgares, Sullivan and King¹⁶⁵ believe the substance is a potent cutaneous sensitizer. They report that the alcoholic solution is more advantageous than the oily suspension. The effect is on epithelial cells, consisting of degenerative action and production of bizarre cell forms interpreted as distorted mitotic figures (similar to colchicine figures). Podophyllo-toxin is probably the substance in the resin of podophyllum responsible for the cytotoxic effect, since the resin in sodium and potassium hydroxide had no effect on condylomata acuminata. I prefer the alcoholic solution. The patient should be warned regarding the subsequent discomfort for three or four days.

CONCLUSION

This review emphasizes the interest in cutaneous medicine evidenced by physicians who are not dermatologists. The majority of these observations were taken from journals not devoted to dermatology.

EDITH E PARRIS, *Assistant Editor*

CASE 35091

PRESENTATION OF CASE

A thirty-one-year-old woman was admitted to the hospital because of a sensation of "tightness" in the epigastrium of eight months' duration.

The patient had been working very hard in a mill in addition to keeping house. She frequently skipped meals, at which times the epigastric distress became worse. A short time later her appetite decreased, and she had to force herself to eat despite the fact that eating relieved the discomfort. Three months before entry she became constipated, requiring daily laxatives ever since. In the eight-month period the weight had fallen from 160 to 110 pounds. She had vomited several times but attributed each episode to the taking of pills, which always gagged her. Weakness and fatigue had both become increasingly severe. There was no history of hematuria or melena. She preferred warm weather, claiming she suffered much from the cold. A basal metabolic rate three weeks before admission was said to have been -25 per cent, another, more recently, +15 per cent, and one on the day of admission +13 per cent. She had been on an iodine preparation for two weeks.

The past history, systemic review and menstrual history were negative.

Aside from showing a poorly nourished woman with evidence of recent weight loss and somewhat warm skin, the physical examination was completely negative. The thyroid gland was not palpable, and no masses were felt in the abdomen.

The temperature was 100.6°F, the pulse 88, and the respirations 22. The blood pressure was normal.

Examination of the urine was negative. Examination of the blood disclosed a red-cell count of 3,600,000, with a hemoglobin of 8.5 gm, and a white-cell count of 8800, with 79 per cent neutrophils. There was moderate constant achromia and variation in size, with slightly smaller than normal red blood cells. The total protein was 6.1 gm per 100 cc, the sodium 130.9 and the chloride 96 milliequiv per liter, and the prothrombin time 21 seconds (normal, 16 seconds). The stools were light colored and guaiac negative.

In the hospital there was little obvious change in the patient's condition. The most striking observation was a persistent spiking temperature, with daily elevations to 102 or 103°F. A sigmoidoscopic examination was negative. The gastric contents were guaiac negative and showed no free hydrochloric acid after alcohol and histamine. A gastrointestinal series showed a normal esophagus. In the stomach there was marked prominence of the rugal folds along both the lesser-curvature and greater-curvature aspects of the upper portion of the stomach (Fig 1). It did not seem to be rigid, and no ulcerations could be identified with certainty. There was no pyloric obstruction, and the duodenum was not remarkable. A film obtained several hours following the gastric meal showed the stomach almost completely empty, with the head of the column in the hepatic flexure. A roentgenogram of the chest was essentially normal except for slight deviation of the trachea to the left at the level of the first thoracic vertebra; there was no evidence of retrosternal position of the thyroid gland.

On the eighth hospital day an abdominal operation was performed

DIFFERENTIAL DIAGNOSIS

DR JOHN R GRAHAM May we see the x-ray films?

DR STANLEY M WYMAN The deviation of the trachea described is seen in the low neck and the upper thorax, but there is no definite mass seen to account for this. The lung fields appear clear except for old, calcified scars in the right lung. The stomach shows a striking change throughout, involving apparently the entire stomach from the cardia to the prepyloric region. This consists of widening of the mucosal folds, with considerable tortuosity of their courses, although there is no frank, gross ulceration. There are multiple, small spicules projecting from the stomach, particularly on the lesser curvature, with at least one on the greater curvature in the prepyloric region. The duodenal cap is not entirely filled on these films, but does not seem remarkable. The spot films add no further information but confirm the previous observations. The spleen seems to extend downward a rather long distance, and the spleen may be at the upper limits of normal. The liver is also very long and slender, but one would not say that it is definitely enlarged. This one film from the barium enema is normal.

DR GRAHAM The essential and fundamental findings and history in this patient seem to me to add up to the following. We have a thirty-one-year-old woman complaining chiefly of gastrointestinal symptoms, distress, loss of appetite, loss of weight and occasional vomiting. She ran a markedly febrile course, at least while in the hospital, and we may assume that perhaps it existed before admission. We have x-ray findings that point to an unusual appearance of the stomach, a moderately severe anemia, and all of these in the presence of a normal white-cell count and differential.

Cast across these fundamental findings are a couple of shadows that lead one off into thinking of other possibilities than the one that I will mention later.

In the first place there was considerable interest in the function of the thyroid gland. We have some confusing basal metabolic rates. The rate seemed to be increasing as the patient took more iodine, and the patient's symptoms in regard to thyroid function are not consistent. She lost weight like a person with hyperthyroidism and suffered from the cold like one with hypothyroidism. In general, my inclination is to believe that these findings in regard to the thyroid gland are probably not of any fundamental importance. I would be at a loss to say what kind of disturbance of the thyroid gland existed, if any, and prefer to think that the thyroid gland in this case is more or less of a red herring.

One thinks for a moment in passing of the history of weight loss, gastrointestinal distress and marked weakness and fatigue, which are mentioned, in the presence of a blood sodium of 130 milliequivalents per liter, and one wonders about adrenal hypofunction. However, lacking any mention of abnormality in the blood pressure or pigmentation or axillary-hair distribution and with positive mention that the menstrual history was normal, I am inclined to think that any disorder of adrenal function was secondary to the cachectic state rather

FIGURE 1

than primary. That makes me go back to the fundamental things, — gastrointestinal symptoms, fever, the x-ray findings pointing to the stomach, the anemia and the normal white-cell count, — and I find myself wondering what disease, obviously a very serious one, could have produced this cachexia and at the same time have caused a fever. Carcinoma of the stomach is usually not accompanied with so much of a febrile reaction, and I think the x-ray picture would be a little unusual, especially since the fluoroscopist described it as a fairly flexible stomach.

If one thinks of prolonged infectious disease, typhoid and the like, it would seem unusual for the

CASE 35091

PRESENTATION OF CASE

A thirty-one-year-old woman was admitted to the hospital because of a sensation of "tightness" in the epigastrium of eight months' duration.

The patient had been working very hard in a mill in addition to keeping house. She frequently skipped meals, at which times the epigastric distress became worse. A short time later her appetite decreased, and she had to force herself to eat despite the fact that eating relieved the discomfort. Three months before entry she became constipated, requiring daily laxatives ever since. In the eight-month period the weight had fallen from 160 to 110 pounds. She had vomited several times but attributed each episode to the taking of pills, which always gagged her. Weakness and fatigue had both become increasingly severe. There was no history of hematuria or melena. She preferred warm weather, claiming she suffered much from the cold. A basal metabolic rate three weeks before admission was said to have been -25 per cent, another, more recently, +15 per cent, and one on the day of admission +13 per cent. She had been on an iodine preparation for two weeks.

The past history, systemic review and menstrual history were negative.

Aside from showing a poorly nourished woman with evidence of recent weight loss and somewhat warm skin, the physical examination was completely negative. The thyroid gland was not palpable, and no masses were felt in the abdomen.

The temperature was 100.6°F, the pulse 88, and the respirations 22. The blood pressure was normal.

Examination of the urine was negative. Examination of the blood disclosed a red-cell count of 3,600,000, with a hemoglobin of 8.5 gm, and a white-cell count of 8800, with 79 per cent neutrophils. There was moderate constant achromia and variation in size, with slightly smaller than normal red blood cells. The total protein was 6.1 gm per 100 cc, the sodium 130.9 and the chloride 96 milliequiv per liter, and the prothrombin time 21 seconds (normal, 16 seconds). The stools were light colored and guaiac negative.

In the hospital there was little obvious change in the patient's condition. The most striking observation was a persistent spiking temperature, with daily elevations to 102 or 103°F. A sigmoidoscopic examination was negative. The gastric contents were guaiac negative and showed no free hydrochloric acid after alcohol and histamine. A gastrointestinal series showed a normal esophagus. In the stomach there was marked prominence of the rugal folds along both the lesser-curvature and greater-curvature aspects of the upper portion of the stomach (Fig 1). It did not seem to be rigid, and no ulcerations could be identified with certainty. There was no pyloric obstruction, and the duodenum was not remarkable. A film obtained several hours following the gastric meal showed the stomach almost completely empty, with the head of the column in the hepatic flexure. A roentgenogram of the chest was essentially normal except for slight deviation of the trachea to the left at the level of the first thoracic vertebra, there was no evidence of retrosternal position of the thyroid gland.

On the eighth hospital day an abdominal operation was performed

DIFFERENTIAL DIAGNOSIS

DR JOHN R GRAHAM May we see the x-ray films?

DR STANLEY M WYMAN The deviation of the trachea described is seen in the low neck and the upper thorax, but there is no definite mass seen to account for this. The lung fields appear clear except for old, calcified scars in the right lung. The stomach shows a striking change throughout, involving apparently the entire stomach from the cardia to the prepyloric region. This consists of widening of the mucosal folds, with considerable tortuosity of their courses, although there is no frank, gross ulceration. There are multiple, small spicules projecting from the stomach, particularly on the lesser curvature, with at least one on the greater curvature in the prepyloric region. The duodenal cap is not entirely filled on these films, but does not seem remarkable. The spot films add no further information but confirm the previous observations. The spleen seems to extend downward a rather long distance, and the spleen may be at the upper limits of normal. The liver is also very long and slender, but one would not say that it is definitely enlarged. This one film from the barium enema is normal.

DR GRAHAM The essential and fundamental findings and history in this patient seem to me to add up to the following. We have a thirty-one-year-old woman complaining chiefly of gastrointestinal symptoms, distress, loss of appetite, loss of weight and occasional vomiting. She ran a markedly febrile course, at least while in the hospital, and we may assume that perhaps it existed before admission. We have x-ray findings that point to an unusual appearance of the stomach, a moderately severe anemia, and all of these in the presence of a normal white-cell count and differential.

Cast across these fundamental findings are a couple of shadows that lead one off into thinking of other possibilities than the one that I will mention later.

In the first place there was considerable interest in the function of the thyroid gland. We have some confusing basal metabolic rates. The rate seemed to be increasing as the patient took more iodine, and the patient's symptoms in regard to thyroid function are not consistent. She lost weight like a person with hyperthyroidism and suffered from the cold like one with hypothyroidism. In general, my inclination is to believe that these findings in regard to the thyroid gland are probably not of any fundamental importance. I would be at a loss to say what kind of disturbance of the thyroid gland existed, if any, and prefer to think that the thyroid gland in this case is more or less of a red herring

One thinks for a moment in passing of the history of weight loss, gastrointestinal distress and marked weakness and fatigue, which are mentioned, in the presence of a blood sodium of 130 milliequivalents per liter, and one wonders about adrenal hypofunction. However, lacking any mention of abnormality in the blood pressure or pigmentation or axillary-hair distribution and with positive mention that the menstrual history was normal, I am inclined to think that any disorder of adrenal function was secondary to the cachectic state rather

FIGURE 1

than primary. That makes me go back to the fundamental things,—gastrointestinal symptoms, fever, the x-ray findings pointing to the stomach, the anemia and the normal white-cell count,—and I find myself wondering what disease, obviously a very serious one, could have produced this cachexia and at the same time have caused a fever. Carcinoma of the stomach is usually not accompanied with so much of a febrile reaction, and I think the x-ray picture would be a little unusual, especially since the fluoroscopist described it as a fairly flexible stomach.

If one thinks of prolonged infectious disease, typhoid and the like, it would seem unusual for the

CASE 35091

PRESENTATION OF CASE

A thirty-one-year-old woman was admitted to the hospital because of a sensation of "tightness" in the epigastrium of eight months' duration.

The patient had been working very hard in a mill in addition to keeping house. She frequently skipped meals, at which times the epigastric distress became worse. A short time later her appetite decreased, and she had to force herself to eat despite the fact that eating relieved the discomfort. Three months before entry she became constipated, requiring daily laxatives ever since. In the eight-month period the weight had fallen from 160 to 110 pounds. She had vomited several times but attributed each episode to the taking of pills, which always gagged her. Weakness and fatigue had both become increasingly severe. There was no history of hematuria or melena. She preferred warm weather, claiming she suffered much from the cold. A basal metabolic rate three weeks before admission was said to have been -25 per cent, another, more recently, +15 per cent, and one on the day of admission +13 per cent. She had been on an iodine preparation for two weeks.

The past history, systemic review and menstrual history were negative.

Aside from showing a poorly nourished woman with evidence of recent weight loss and somewhat warm skin, the physical examination was completely negative. The thyroid gland was not palpable, and no masses were felt in the abdomen.

The temperature was 100.6°F, the pulse 88, and the respirations 22. The blood pressure was normal.

Examination of the urine was negative. Examination of the blood disclosed a red-cell count of 3,600,000, with a hemoglobin of 8.5 gm, and a white-cell count of 8800, with 79 per cent neutrophils. There was moderate constant achromia and variation in size, with slightly smaller than normal red blood cells. The total protein was 6.1 gm per 100 cc, the sodium 130.9 and the chloride 96 milliequiv per liter, and the prothrombin time 21 seconds (normal, 16 seconds). The stools were light colored and guaiac negative.

In the hospital there was little obvious change in the patient's condition. The most striking observation was a persistent spiking temperature, with daily elevations to 102 or 103°F. A sigmoidoscopic examination was negative. The gastric contents were guaiac negative and showed no free hydrochloric acid after alcohol and histamine. A gastrointestineal series showed a normal esophagus. In the stomach there was marked prominence of the rugal folds along both the lesser-curvature and greater-curvature aspects of the upper portion of the stomach (Fig 1). It did not seem to be rigid, and no ulcerations could be identified with certainty. There was no pyloric obstruction, and the duodenum was not remarkable. A film obtained several hours following the gastric meal showed the stomach almost completely empty, with the head of the column in the hepatic flexure. A roentgenogram of the chest was essentially normal except for slight deviation of the trachea to the left at the level of the first thoracic vertebra, there was no evidence of retrosternal position of the thyroid gland.

to do what I thought was the most radical operation for cancer of the stomach on the basis that we might be dealing with that disease. A total gastrectomy was done, and it looked as if the stomach grossly were completely involved except possibly the part just proximal to the pylorus.

Another interesting clinical observation is that almost immediately after operation the temperature came down to normal. It was not as high the next day as it had been the day before operation. Then she ran for ten days a perfectly flat normal chart. After that she began to run another wave of fever, which was coincident with the usual dose of x-ray treatment, which she has been having and has just completed. Then we gave penicillin empirically, and after a period of ten days the temperature came down, and she then ran another normal temperature for a period followed by another short episode of fever. And now, once again, the temperature is down. Whether that has any significance as far as the primary disease goes, I do not know. It had no correlation with any obvious complication — no abscess, empyema, pulmonary infection or anything that we could find.

At one time there was a small accumulation of air and fluid beneath the left leaf of the diaphragm, but after a period of time it disappeared. The patient is going home tomorrow.

DR ADAMS: Did the blood picture improve?

DR SWEET: She continued to look more and more miserable as x-ray treatment progressed. After what was interpreted as a normal hemoglobin level before, during and after operation, the hemoglobin fell to 6 gm during the course of the treatment. She is having more transfusions in anticipation of discharge. She was very much nauseated by the x-ray therapy. We have hopes that she will improve now that we have stopped x-ray treatment.

Incidentally, we took out the spleen and terminal half of the pancreas, not because they were involved but because it was technically the only way I could get all the lymph nodes around the celiac axis.

DR MALLORY: We found that the stomach was entirely involved with tumor. There seemed to be two centers of tumor from which the lesion spread to involve virtually all the mucosa. One of these was shallowly ulcerated. A number of lymph nodes were obviously replaced by tumor, whereas others were normal. The histologic picture showed a very undifferentiated tumor, with a great many multinucleated cells in it, and our diagnosis was lymphoma of the Hodgkin's-sarcoma type. Some of the lesions in the lymph nodes were more characteristic of Hodgkin's disease than the stomach itself. The spleen was entirely uninvolved.

DR BENEDICT: I think this case represents one of the most important potential uses for the new gastroscope — namely, the differential diagnosis between gastritis, lymphoma and diffuse carcinoma

of the stomach. We have done 31 cases, of which 18 had chronic gastritis and 2 acute and chronic gastritis, and 8 showed normal stomachs, 1 lymphoma and 1 carcinoma.

DR MALLORY: Very frequently in lymphoma of the stomach the lesion is diffuse and grossly shows mucosal folds that, by x-ray examination, are indistinguishable from the hypertrophic type of gastritis.

DR SWEET: One of our medical staff who saw the patient raised the question of obtaining a bone-marrow biopsy. I wonder if we had done it whether it would have assisted us in making the diagnosis.

DR ADAMS: Before the routine studies were completed, we thought that a bone-marrow biopsy might be necessary to exclude leukemia. It would have been done had the other findings not crystallized the situation for us. I do not believe that it would have helped establish a diagnosis of lymphoma unless, in doing the biopsy, one was fortunate enough to stick the needle into a lymphomatous lesion in the bone marrow.

If Dr Benedict is including this case in a statistical study, he should not, in my opinion, include it as a case clinically diagnosed as gastritis. Before operation we were quite certain that we were dealing with a malignant lesion, probably lymphoma. The clinical diagnosis of gastritis was not considered.

If Dr Benedict is thinking in terms of statistics, I do not believe he should include this as a case of clinical gastritis in which lymphoma was discovered because we were quite certain we were dealing with a malignant lesion.

DR SWEET: Yes, and in the stomach.

DR WYMAN: The only point I want to make about x-ray treatment and anemia is that from our point of view it seems probable that she had extensive bone-marrow disease, which was accounting for the anemia, and this was not produced by x-ray treatment.

DR SWEET: Perhaps I gave the wrong impression. I did not mean to imply that there was a causal relation, it was merely an observation.

CASE 35092

PRESENTATION OF CASE

A seventy-nine-year-old retired mechanic entered the hospital because of vomiting, weakness and weight loss.

The patient was first seen in the Out-Patient Department seven years before, when he complained of intermittent attacks of epigastric burning and fullness of three or four years' duration. The discomfort was relieved by food and alkalis. There was some weight loss, but no nausea, vomiting or melena. Physical examination at that time revealed tenderness with some resistance in the epigastrium. An x-ray examination revealed the

patient to have had so many symptoms directly related to the gastrointestinal tract

One might consider liver disease, but I think liver disease presenting such marked fever and so much interference with gastrointestinal function and weight loss would have other earmarks that would point to the liver—either enlargement, telangiectasis, positive laboratory findings or jaundice. I am inclined to think this was not primarily liver disease.

The condition that in my mind answers the cachexia, the x-ray findings and the febrile course of the disease is one of the lymphoma or Hodgkin's group, and I would imagine that of these lymphoma is more apt to involve the stomach. I think these findings in the stomach were perfectly consistent with that diagnosis, and I would guess that, in addition to the involvement of the stomach, since there had been so much fever, the surgeon found involvement of the mesenteric and possibly retroperitoneal lymph nodes. I believe it is the experience of the X-ray Department that in lymphoma, when there is fever with no obvious explanation, the seat of the trouble is apt to be in these obscurely hidden lymph nodes. I am going to commit myself to a diagnosis of one of the lymphoma group, involving the stomach and probably the mesenteric and retroperitoneal lymph nodes.

DR TRACY B MALLORY: Would you like to add anything, Dr Adams?

DR F DENNETTE ADAMS: No, but I might say that my final reasoning was similar to Dr Graham's.

DR WYMAN: From the x-ray point of view, without the available clinical and laboratory data, one would have to consider hypertrophic gastritis also because of the enlarged gastric rugae.

DR ALLEN G BRAILEY: The fever was slightly high, was it not, to be explained on the basis of lymphoblastoma?

DR GRAHAM: I think it was consistent with that diagnosis. The thing that bothered me about it was that it was described as a spiking temperature, whereas the Pel-Ebstein type is less apt to be up and down. I am sure it is possible because I have seen it as high as this and even higher.

DR EDWARD B BENEDICT: We did a gastroscopy on this patient. There was no normal mucosa visible in any part of the stomach. The gastric wall presented a nodular appearance throughout. The angulus was distorted and somewhat rigid, and the gastric wall did not respond normally to air inflation. In other words, there was some evidence of rigidity. My first bet from the gross appearance was lymphoma, and I was fortunate that with the new operating gastroscope it was possible to get a satisfactory biopsy.

CLINICAL DIAGNOSIS

Lymphoma of stomach?

DR GRAHAM'S DIAGNOSIS

Lymphoma of stomach and mesenteric and retroperitoneal lymph nodes

ANATOMICAL DIAGNOSIS

Malignant lymphoma, Hodgkin's-sarcoma type, of stomach

PATHOLOGICAL DISCUSSION

DR MALLORY: Dr Benedict obtained a biopsy that clearly showed the presence of a malignant tumor. We were unable from the biopsy to make a certain diagnosis as to the type of neoplasm. We hesitated between carcinoma and lymphoma and eventually decided that it was a little more probable that it was carcinoma. Later we had reason to change our minds because Dr Sweet operated on the patient, and he will tell us the operative findings.

DR RICHARD H SWEET: May I say a word or two about the clinical appearance. This patient was sent to the hospital through my office. I did not see her before she arrived. She was referred to me by a physician who has always sent me thyroid cases and rarely anything else. At any rate, that is why the iodine entered the picture, because he had made a diagnosis of thyrotoxicosis and started her on iodine before she came to the hospital. We thought the elevation of the temperature might explain the increased basal metabolic rate. We found in the hospital that it was not as high as reported outside and immediately discarded that diagnosis.

I must confess that if we had not done a gastroscopy and not had the technical skill of Dr Benedict to obtain a biopsy through this new mysterious instrument of his, I would have made a definite diagnosis, purely on clinical grounds, of lymphoma of the stomach. When I heard that Dr Mallory, whose opinion I respect, was leaning toward carcinoma, I said "Well, I suppose it is carcinoma." When we saw the stomach at operation we could not tell grossly whether it was lymphoma or carcinoma. The only thing different was—this is from the clinical surgeon's point of view, not the pathologist's—the gross appearance of the lymph nodes was not like that in metastatic carcinoma. They were large, pink, juicy-looking things—more like inflammation or lymphoma. There was no evidence of lymph nodes in the mesentery, and nothing abnormal in the spleen or liver. We did the operation transthoracically or rather abdominotheracically and had an opportunity to investigate the left chest. There was nothing wrong there. But to extirpate as much of the disease as possible I took out the whole omentum and all the lymph nodes along both curvatures of the stomach, along the left gastric artery, and all the nodes around the abdominal segment of the esophagus. I endeavored

to do what I thought was the most radical operation for cancer of the stomach on the basis that we might be dealing with that disease. A total gastrectomy was done, and it looked as if the stomach grossly were completely involved except possibly the part just proximal to the pylorus.

Another interesting clinical observation is that almost immediately after operation the temperature came down to normal. It was not as high the next day as it had been the day before operation. Then she ran for ten days a perfectly flat normal chart. After that she began to run another wave of fever, which was coincident with the usual dose of x-ray treatment, which she has been having and has just completed. Then we gave penicillin empirically, and after a period of ten days the temperature came down, and she then ran another normal temperature for a period followed by another short episode of fever. And now, once again, the temperature is down. Whether that has any significance as far as the primary disease goes, I do not know. It had no correlation with any obvious complication — no abscess, empyema, pulmonary infection or anything that we could find.

At one time there was a small accumulation of air and fluid beneath the left leaf of the diaphragm, but after a period of time it disappeared. The patient is going home tomorrow.

DR ADAMS: Did the blood picture improve?

DR SWEET: She continued to look more and more miserable as x-ray treatment progressed. After what was interpreted as a normal hemoglobin level before, during and after operation, the hemoglobin fell to 6 gm during the course of the treatment. She is having more transfusions in anticipation of discharge. She was very much nauseated by the x-ray therapy. We have hopes that she will improve now that we have stopped x-ray treatment.

Incidentally, we took out the spleen and terminal half of the pancreas, not because they were involved but because it was technically the only way I could get all the lymph nodes around the celiac axis.

DR MALLORY: We found that the stomach was entirely involved with tumor. There seemed to be two centers of tumor from which the lesion spread to involve virtually all the mucosa. One of these was shallowly ulcerated. A number of lymph nodes were obviously replaced by tumor, whereas others were normal. The histologic picture showed a very undifferentiated tumor, with a great many multinucleated cells in it, and our diagnosis was lymphoma of the Hodgkin's-sarcoma type. Some of the lesions in the lymph nodes were more characteristic of Hodgkin's disease than the stomach itself. The spleen was entirely uninvolved.

DR BENEDICT: I think this case represents one of the most important potential uses for the new gastroscope — namely, the differential diagnosis between gastritis, lymphoma and diffuse carcinoma

of the stomach. We have done 31 cases, of which 18 had chronic gastritis and 2 acute and chronic gastritis, and 8 showed normal stomachs, 1 lymphoma and 1 carcinoma.

DR MALLORY: Very frequently in lymphoma of the stomach the lesion is diffuse and grossly shows mucosal folds that, by x-ray examination, are indistinguishable from the hypertrophic type of gastritis.

DR SWEET: One of our medical staff who saw the patient raised the question of obtaining a bone-marrow biopsy. I wonder if we had done it whether it would have assisted us in making the diagnosis.

DR ADAMS: Before the routine studies were completed, we thought that a bone-marrow biopsy might be necessary to exclude leukemia. It would have been done had the other findings not crystallized the situation for us. I do not believe that it would have helped establish a diagnosis of lymphoma unless, in doing the biopsy, one was fortunate enough to stick the needle into a lymphomatous lesion in the bone marrow.

If Dr Benedict is including this case in a statistical study, he should not, in my opinion, include it as a case clinically diagnosed as gastritis. Before operation we were quite certain that we were dealing with a malignant lesion, probably lymphoma. The clinical diagnosis of gastritis was not considered.

If Dr Benedict is thinking in terms of statistics, I do not believe he should include this as a case of clinical gastritis in which lymphoma was discovered because we were quite certain we were dealing with a malignant lesion.

DR SWEET: Yes, and in the stomach.

DR WYMAN: The only point I want to make about x-ray treatment and anemia is that from our point of view it seems probable that she had extensive bone-marrow disease, which was accounting for the anemia, and this was not produced by x-ray treatment.

DR SWEET: Perhaps I gave the wrong impression. I did not mean to imply that there was a causal relation, it was merely an observation.

CASE 35092

PRESENTATION OF CASE

A seventy-nine-year-old retired mechanic entered the hospital because of vomiting, weakness and weight loss.

The patient was first seen in the Out-Patient Department seven years before, when he complained of intermittent attacks of epigastric burning and fullness of three or four years' duration. The discomfort was relieved by food and alkalis. There was some weight loss, but no nausea, vomiting or melena. Physical examination at that time revealed tenderness with some resistance in the epigastrium. An x-ray examination revealed the

esophagus to be normal except for slight compression from a tortuous aorta just above the diaphragm. The fundus of the stomach appeared to be deformed, probably owing to extrinsic pressure. The pylorus opened readily, outlining a markedly deformed duodenal cap, with several large pouches on each curvature. In the narrowest portion of the cap there was a 1-cm crater, probably on the posterior wall. Diet and antacids gave relief, but approximately a year later he became weak, vomited black liquid and passed a black stool. He was anemic, with a hemoglobin of 8.1 gm, but he preferred not to be hospitalized. Several weeks later an x-ray film showed a deformed duodenum with a tiny ulcer crater on the posterior wall. On rest, diet and antacids he improved but remained weak. Three years before admission epigastric discomfort recurred following dietary indiscretions. An x-ray film again showed a deformed duodenum with an active ulcer. Five months previous to admission weakness, weight loss and anorexia developed, and later he had a single episode of severe epigastric pain, which "doubled him up" and required an injection by his doctor. He became more anorexic, weaker and finally bedridden. There was no hematemesis or melena, but he vomited all food he ingested in the two weeks prior to admission. Five days before entry he began to hiccup and developed pain in the left shoulder.

Physical examination showed a wasted man hiccuping constantly. The breath was not uremic. The tongue was coated and dry. There was marked kyphosis. The heart was slightly enlarged. The liver edge was percussible two fingerbreadths below the costal margin. There was tenderness in the left upper quadrant, and a hard, irregular edge could be felt under the left rib margin.

The temperature was 99.6°F, and the pulse 68. The blood pressure was 110 systolic, 70 diastolic.

The urine gave a ++ test for albumin, and the sediment contained many granular casts, occasional white blood cells and rare red blood cells. The hemoglobin was 11.5 gm. The white-cell count was 17,200, with 87 per cent neutrophils. The serum protein was 6.3 gm per 100 cc. The chloride was 97 milliequiv per liter, and the nonprotein nitrogen 5.4 mg and the fasting blood sugar 136 mg per 100 cc. The prothrombin time was 18 seconds (normal, 15 seconds). A gastrointestinal series was reported as follows:

The esophagus is quite normal as to form and function, except for the fact that it retains barium longer than usual, apparently owing to pressure upon its lower end by some thing beneath the diaphragm, which also is consistent with pressure and deformity of the fundus of the stomach. The fundus and body of the stomach are displaced anteriorly. There is an irregular pooling of barium in the fundus just below the cardia. Within the hollow of the displaced stomach there are several areas of translucency that look like air, a few other areas look like barium. These dense flecks are seen on the film made several years ago. The duodenal bulb is constantly deformed in the manner characteristic of ulcer. An ulcer crater 0.5 cm in size is present.

A chest film showed scoliosis of the spine and mild arthritic changes.

During the hospital stay the temperature spiked daily to 101 and 102°F, with an average pulse rate of about 105. Examination of the blood on the fourth day showed a white-cell count of 33,200, with "marked neutrophilia and toxic granules." Attempts to pass a tube from the esophagus into the stomach were unsuccessful. On the sixth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR HORATIO ROGERS: I think we can assume that eleven years before admission this man had ulcer symptoms, seven years before admission he still had ulcer symptoms, and x-ray films demonstrated duodenal ulcer. One year later he had a gastrointestinal hemorrhage, presumably from the duodenal ulcer, three years before admission he still had ulcer symptoms, and x-ray examination demonstrated an active duodenal ulcer. All this past history would be consistent with a simple duodenal ulcer if it were not for that one x-ray note about the fundus of the stomach being deformed by extrinsic pressure seven years before admission.

It seems that the present illness began five months before entry. Within five months there was progressive weight loss, weakness and anorexia. The patient was seventy-nine years old, so that one immediately thinks of cancer, possibly in the stomach. Then he had an episode of severe epigastric pain, doubling him up and requiring an injection. We do not know just how long before admission that was, but presumably very recently. That makes me wonder about perforation of the old ulcer or possibly hemorrhage into a cyst. It may have been a cyst behind the stomach, that would go with the x-ray description of extrinsic deformity of the

stomach Hemorrhage into a pancreatic cyst could cause a severe, acute episode of epigastric pain, such as this man had Then he developed vomiting, and he vomited everything Whether that was really vomiting or regurgitation may be important, because if his stomach was obstructed at the cardia, it could not have been vomiting, it must have been regurgitation Then he developed hiccuping and pain in the left shoulder, which suggests irritation of the left leaf of the diaphragm So from the history alone we might assume that he had something in the lesser peritoneal cavity that formed the x-ray shadow that deformed the stomach and pushed it forward and was presumably associated with an acute episode of epigastric pain from which he rapidly went downhill

I would like to see the x-ray films because there are a number of things I do not understand, particularly the note about flecks of barium seen in the examination years previously in the hollow of the displaced stomach Does that mean in the stomach itself?

DR STANLEY M WYMAN There are only three films remaining from the x-ray examination of this patient, unfortunately The first film was taken seven years before the last The second film was taken four years after the first, and three before the last The flecks of density described are seen at this point on the original examination lying apparently quite close to the stomach There is definite compression of this portion of the cardia, with a suggestion of a soft-tissue density in the adjacent region The deformity of the duodenal bulb is imperfectly visualized, but I believe it is present The second film taken four years later shows the fleck of density to have been displaced more posteriorly The films were taken in quite similar projection I believe this is a true observation, particularly in view of the last film, which shows the density to have been pushed still farther posteriorly and downward The second film shows a suggestion of a sharp angle in the upper part of the stomach and, again, a soft-tissue mass, which on the last film extends along the midbody down close to the angle, in a hemispherical fashion, and indenting the cardia The small shadows of rarefaction seen here, I believe, lie in the soft-tissue mass and probably represent gas The general configuration and contour of this lesion, with the sharp angle where the mass joins

normal stomach, are consistent with an adherent mass or an intramural mass

DR ROGERS Do we have to suppose that these flecks are barium, or can we think that they are calcium?

DR WYMAN I think calcium is perhaps a better bet

DR ROGERS On physical examination the patient was emaciated and had a hemoglobin of 8.1 gm, which is less anemia than one would expect with cancer of the stomach of this extent He had casts and albumin in the urine and nonprotein nitrogen of 54 mg per 100 cc., indicating kidney damage, but not enough to make me suspect the kidney as the primary source of his trouble He had an elevated temperature and a rising white-cell count, which would make one think of either sepsis or necrosis He had a prothrombin time only slightly elevated, and the liver edge could be palpated two fingerbreadths below the costal margin It does not indicate anything very important associated with the liver to me The blood sugar was 136 mg per 100 cc., and the top normal would be 100 mg, so that is a definite elevation and immediately makes one think of the carbohydrate metabolism and wonder about the function of the pancreas We do not have any amylase or lipase or glucose tolerance report so probably that was not seriously considered on the wards

Then we come to the hard, irregular, tender mass in the left upper quadrant Apparently that is the thing we have to guess the nature of Was it a malignant tumor in the stomach itself? I should think that the slightness of his anemia, his lack of bleeding and the seven-year duration of gastric deformity were all against it It could be retroperitoneal malignant sarcoma of some form, but the present course seems to have been rapidly progressive, yet we have x-ray evidence of its presence seven years before admission It could hardly have been a malignant tumor going on all that time A possible explanation would be a mass that remained benign for several years and then more recently became malignant We could explain the acute episode just before admission on the basis of either necrosis of a malignant tumor or hemorrhage into a malignant pancreatic cyst I think that cancer of the body or tail of the pancreas would be my best bet There are a number of things about cancer of the tail of the pancreas that are characteristic and ap-

esophagus to be normal except for slight compression from a tortuous aorta just above the diaphragm. The fundus of the stomach appeared to be deformed, probably owing to extrinsic pressure. The pylorus opened readily, outlining a markedly deformed duodenal cap, with several large pouches on each curvature. In the narrowest portion of the cap there was a 1-cm crater, probably on the posterior wall. Diet and antacids gave relief, but approximately a year later he became weak, vomited black liquid and passed a black stool. He was anemic, with a hemoglobin of 8.1 gm, but he preferred not to be hospitalized. Several weeks later an x-ray film showed a deformed duodenum with a tiny ulcer crater on the posterior wall. On rest, diet and antacids he improved but remained weak. Three years before admission epigastric discomfort recurred following dietary indiscretions. An x-ray film again showed a deformed duodenum with an active ulcer. Five months previous to admission weakness, weight loss and anorexia developed, and later he had a single episode of severe epigastric pain, which "doubled him up" and required an injection by his doctor. He became more anorexic, weaker and finally bedridden. There was no hematemesis or melena, but he vomited all food he ingested in the two weeks prior to admission. Five days before entry he began to hiccup and developed pain in the left shoulder.

Physical examination showed a wasted man hiccuping constantly. The breath was not uremic. The tongue was coated and dry. There was marked kyphosis. The heart was slightly enlarged. The liver edge was percussible two fingerbreadths below the costal margin. There was tenderness in the left upper quadrant, and a hard, irregular edge could be felt under the left rib margin.

The temperature was 99.6°F, and the pulse 68. The blood pressure was 110 systolic, 70 diastolic.

The urine gave a ++ test for albumin, and the sediment contained many granular casts, occasional white blood cells and rare red blood cells. The hemoglobin was 11.5 gm. The white-cell count was 17,200, with 87 per cent neutrophils. The serum protein was 6.3 gm per 100 cc. The chloride was 97 milliequiv per liter, and the nonprotein nitrogen 54 mg and the fasting blood sugar 136 mg per 100 cc. The prothrombin time was 18 seconds (normal, 15 seconds). A gastrointestinal series was reported as follows:

The esophagus is quite normal as to form and function, except for the fact that it retains barium longer than usual, apparently owing to pressure upon its lower end by something beneath the diaphragm, which also is consistent with pressure and deformity of the fundus of the stomach. The fundus and body of the stomach are displaced anteriorly. There is an irregular pooling of barium in the fundus just below the cardia. Within the hollow of the displaced stomach there are several areas of translucency that look like air, a few other areas look like barium. These dense flecks are seen on the film made several years ago. The duodenal bulb is constantly deformed in the manner characteristic of ulcer. An ulcer crater 0.5 cm in size is present.

A chest film showed scoliosis of the spine and mild arthritic changes.

During the hospital stay the temperature spiked daily to 101 and 102°F, with an average pulse rate of about 105. DOCTORS' PROGRAM

THE meeting of the Planning Committee of the American Medical Association was held, as scheduled, in Chicago on February 12. Composed of the officers of the Association and representatives of the Board of Trustees and the House of Delegates, the committee was augmented by the secretary and one other member of each state medical society and other interested persons. Its purpose was to present a plan of action for the American Medical Association to follow in bettering its relations with the public and in acquainting the public with the practices of American medicine, and to consider a constructive program for improving the distribution of medical care in this country.

These objectives are those for which many of the critics of the Association have been clamoring since the assessment was announced in December and for the preparation of which adequate time was necessary.

A revitalized public-relations plan is in the hands of the firm of Whitaker and Baxter, of San Francisco, which has opened offices for the purpose in Chicago. The plan is first to neutralize the smear attack on the subject of lobbying and a "slush fund" that has been launched against the Association, and next to organize an educational campaign that will reach the people of the United States through the individual members of the Association and all interested persons and organizations. This campaign will emphasize the desirability of free enterprise in medicine and the extension of voluntary prepayment plans, as opposed to the principle of compulsory health insurance.

These are the purposes for which the assessment levied by the Association is already being expended, every dollar of which will be reported in a check-by-check accounting to the Association, with financial reports available for Government inspection at any time.

In addition, a twelve-point program for the advancement of medicine and public health is proposed. These points, in brief, consist of

- 1 Creation of a federal Department of Health of Cabinet status with a secretary who is a Doctor of Medicine, and the co-ordination and integration of all federal health activities under it, except for those of the medical services of the armed forces.

- 2 Promotion of medical research through a National Science Foundation, with grants to private institutions.

- 3 Further development and wider coverage by voluntary hospital and medical care plans to meet the costs of illness, with aid through the states to the indigent and medically indigent.

- 4 Establishment in each state of a medical care authority to receive and administer funds with proper representation of medical and consumer interest.

pear in this case. For instance, the surprisingly high hemoglobin for such a sick man, the hyperglycemia, the extreme weight loss and the rapid downhill course at the end. He did not have jaundice, the other common sign of pancreatic cancer, because the mass was not near the common duct.

DR J H MEANS Could this have been a leiomyoma of the stomach? My recollection is that they may exist in benign fashion for a number of years and take on rapid malignant growth terminally. The roentgenologist said it seemed as if it were in the wall of the stomach, which is where leiomyoma would develop. It could have perforated, I suppose, as a terminal event.

DR WYMAN I think that is an excellent suggestion and should be considered most seriously. Perhaps I did not emphasize sufficiently the pockets of probable gas lying in the mass. They have to be explained by gas-forming organisms or, more logically, by the entrance of gas into the mass from a gas-containing viscus.

DR TRACY B MALLORY Dr FitzHugh, would you like to comment?

DR GREENE FITZHUGH I thought that the tumor did not originate in the stomach and believed as Dr Rogers did that the best possibility was the pancreas.

DR PERRY J CULVER Would deposits of fat reduce x-ray opacity enough to cause such spots of radiolucency?

DR WYMAN Fat deposits have the same x-ray density as air, but they are not present on the original two films and, therefore, one must assume that they have developed since then.

DR CULVER I was thinking of fat necrosis with pancreatic tumor.

DR WYMAN I do not believe it would produce this appearance.

DR MALLORY Fat necrosis would probably cause a dense shadow because it tends to calcify very fast.

CLINICAL DIAGNOSIS

Perforated malignant tumor, with abscess formation

DR ROGERS'S DIAGNOSES

Malignant degeneration of pancreatic cyst
Duodenal ulcer, old

ANATOMICAL DIAGNOSES

Neurofibrosarcoma of stomach, with metastases to liver and perforation into abdominal cavity
Peritonitis, acute, generalized, mild
Arteriosclerosis, generalized, moderate
Emphysema, pulmonary

PATHOLOGICAL DISCUSSION

DR MALLORY This patient was explored in the very forlorn hope that there might be a localized abscess that could be drained. At operation Dr Parsons found a large tumor mass arising from the lesser curvature of the stomach, firmly attached to it. He was unable to do anything but take a biopsy. There was slight peritonitis present, but the patient died within twenty-four hours.

At autopsy a large tumor was found occupying about half the lesser curvature, lying almost entirely intramurally. Its center was eroded, and perforation had resulted. It was a spindle-cell sarcoma — we thought more likely fibrosarcoma than leiomyosarcoma. That differentiation is often a difficult one to make. There was one single large metastasis to the liver — a round spherical nodule, nearly 6 cm in diameter. No other metastases were found. We were able to find the scar of his old duodenal ulcer, which seemed entirely healed. The other findings were only those consistent with his age, such as generalized arteriosclerosis and pulmonary emphysema, neither of them severe.

It is possible that Government may so reform its methods as to make a vast federal insurance scheme run smoothly, efficiently and economically, but it is the policyholders who would be taking the uncalculated risk — under compulsion

Certain conclusions are obvious. Momentous decisions are in the making, and the order changeth, in one way or another. It must be accepted that all honest advocates either of Government control and compulsory insurance or of free enterprise and voluntary insurance have the same interest at heart — the best possible medical care for all the people who can be reached. Each faction, if factions there must be, may make one of its greatest contributions to the attainment of this common goal by trying to understand and appraise the opinions of the other.

There can be no disagreement with Dr Butler's closing sentence in which, referring to the Suffolk District and the Massachusetts Medical societies, he writes "the past history of both societies amply justifies the expectation that considered thought will result in much needed tolerant discussion, intelligent decisions and constructive action."

NITROGEN CYCLE

THE world is full of headaches these days, and one of the major ones that will remain after a *modus vivendi* has been achieved between Russia and the rest of the world, the Jews and Arabs have been appeased in Palestine and some sort of low-cost medical care has been provided for our own people is the truly frightening contemporary fulfillment of the dire prophecies made exactly one hundred and fifty years ago by Thomas R. Malthus in his "Essay on Population as it Affects the Future Improvement of Society." The world is running out of food.

Hopefully the UN presents a possible solution. Among that body's multifarious assortment of organizations to plan for a brave new future are the WHO, or World Health Organization, and the FAO, or Food and Agricultural Organization. Experts in the two organizations are convinced that a world problem of such vast and complicated nature as the present universal food shortage cannot possibly

be solved by any short-term emergency schemes. Something more effective and more enduring than mere relief projects must be undertaken. WHO and FAO propose action for more food through better health.* It seems that an important reason why the world's farmers cannot produce enough food is that they are not enjoying the good health usually attributed to tillers of the soil.

At least ten million acres of potentially rich agricultural land are now being worked by disease-ridden people. The two organizations estimate that the enduring and effective project they have in mind could be carried out over this area at a cost of only twenty cents per acre per year. During a trial period of five years this would require the expenditure of only ten million dollars.

What can be done for these ten million acres at twenty cents each? The answer is simply to spray them with DDT. Malaria, the greatest scourge, might by this simple expedient be wiped out entirely or at least controlled beyond the point of being a real danger any longer. Thus, the low agricultural output would be increased per man and per acre, contributing directly to the alleviation of the world food scarcity and creating almost immediately a spirit of enterprise and self-respect among men who had previously believed that they were the slaves of their environment and not its masters.

WHO and FAO suggest that introduction of proper methods in the combined use of agricultural machinery, adequate draft power, correct fertilizers, and so forth is also desirable, and perhaps might be accomplished to some extent at the same rate of twenty cents per acre. The plan seems at least worth trying.

NATIONAL GUARD NEEDS MEDICAL PERSONNEL

ATTENTION is directed to the communication from Colonel Chamberlin published elsewhere in this issue of the *Journal*. Eligible members of the profession, somewhat blinded by the publicity that is shed on the medical-personnel requirements of the country's expanding military and naval establishments, may fail to realize the opportunities that the National Guard has to offer.

*WHO Newsletter, Vol. 2 No. 10 October 1948. New York: Public Information Office, World Health Organization.

5 Encouragement of prompt development of diagnostic facilities, health centers and hospital services, locally originated for areas in which the need can be shown

6 Establishment and improvement of local public-health units and services, with remuneration of health officials commensurate with their responsibility

7 The development of a program of mental hygiene with aid to mental-hygiene clinics in suitable areas

8 Health education programs administered through suitable state and local health and medical agencies

9 Provision of facilities for care and rehabilitation of the aged and those with chronic disease and various other groups not covered by existing proposals

10 Integration of veterans' medical care and hospital facilities with other medical care and hospital programs

11 Greater emphasis on the program of industrial medicine, with increased safeguards against industrial hazards and prevention of accidents occurring on the highway, in the home and on the farm

12 Adequate support, with funds free from political control, of the medical, dental and nursing schools and other institutions necessary for the training of specialized personnel required in the provision and distribution of medical care

Obviously any such program or parts of it to become effective will require legislation, which will presumably be proposed at the proper time

PUBLIC FINANCING IN MEDICINE

THE discourse on public financing of medical education, research, health and medical care, delivered last May by Dr Allan M Butler before the Suffolk District Medical Society and published elsewhere in this issue of the *Journal*, presents astutely and temperately certain arguments in favor of compulsory health insurance

It so happens, nevertheless, that the majority of the medical profession is at present opposed, and

it believes with reason, to this method of payment for medical services. What its attitude may be five, fifteen or fifty years hence is another matter, since it is the present that is under consideration. It is freely admitted, however, that principles having to do with the distribution of medical care that are accepted today were anathema ten or fifteen years ago.

The fact that in 1946 the Government spent \$1,200,000,000 for health and medical care is taken by Dr Butler as "a measure of the failure of philanthropy and private charity to meet the needs." Presumably the expenditures of the Veterans Administration are included in this figure, but aside from this no estimate is available as to how much of the colossal outlay was necessary, or how wisely and economically it was made. If this vast sum was expended with caution and judgment, and with due regard to conservation of the country's resources, then the employment of some part of it is certainly acceptable so far as present concepts are concerned. This applies especially to those allocations having to do with public health, with the care of communicable disease and mental illness, and to a considerable degree with research. There is, however, a line, indistinct as it may be, beyond which governmental encroachment may be justly considered as dangerous in that it may jeopardize the quality of medical care. There is still occasion, in our imperfect society, for skepticism regarding the efficiency of Government methods.

Published sections of the Hoover investigation give substance to this skepticism, as where it reports, in relation to the construction of Veterans Administration Hospitals, "The federal Government is assuming uncalculated obligations without any understanding of their ultimate cost, the lack of necessary professional manpower to carry them out, or their adverse effect upon the hospital system of the country." And again, "[there is a] pattern of duplication of physical facilities, waste of scarce medical personnel, and unwarranted construction of new facilities—all resulting primarily from the lack of a central plan for federal medical care."

It is possible that Government may so reform its methods as to make a vast federal insurance scheme run smoothly, efficiently and economically, but it is the policyholders who would be taking the uncalculated risk — under compulsion

Certain conclusions are obvious. Momentous decisions are in the making, and the order changeth, in one way or another. It must be accepted that all honest advocates either of Government control and compulsory insurance or of free enterprise and voluntary insurance have the same interest at heart — the best possible medical care for all the people who can be reached. Each faction, if factions there must be, may make one of its greatest contributions to the attainment of this common goal by trying to understand and appraise the opinions of the other.

There can be no disagreement with Dr. Butler's closing sentence in which, referring to the Suffolk District and the Massachusetts Medical societies, he writes "the past history of both societies amply justifies the expectation that considered thought will result in much needed tolerant discussion, intelligent decisions and constructive action."

NITROGEN CYCLE

THE world is full of headaches these days, and one of the major ones that will remain after a *modus vivendi* has been achieved between Russia and the rest of the world, the Jews and Arabs have been appeased in Palestine and some sort of low-cost medical care has been provided for our own people is the truly frightening contemporary fulfillment of the dire prophecies made exactly one hundred and fifty years ago by Thomas R. NATIONAL GUARD NEEDS MEDICAL PERSONNEL

ATTENTION is directed to the communication from Colonel Chamberlin published elsewhere in this issue of the *Journal*. Eligible members of the profession, somewhat blinded by the publicity that is shed on the medical-personnel requirements of the country's expanding military and naval establishments, may fail to realize the opportunities that the National Guard has to offer.

**WHO Newsletter*, Vol. 2, No. 10, October 1948. New York, Public Information Office, World Health Organization.

Enrolled in this permanent organization, trained to serve in the event of civil disaster as well as in that of wartime emergency, the medical officer has an unusual opportunity for discharging his military obligations in his own chosen outfit. Colonel Chamberlin's letter outlines the details of service and of pay for both physicians and medical students, as well as the important point of retirement income.

LITHIUM CHLORIDE

A small number of patients on low sodium diets who are receiving a salt substitute — Westsal — (Wess-sal) have been reported to have had toxic symptoms, especially muscle tremors, weakness, inco-ordination and gastrointestinal disturbances, possibly due to lithium. Any information concerning the occurrence of very rare fatalities is highly inconclusive.

The manufacturers are investigating the situation. Any physician who can report on the successful use of the preparation or its toxic effects should communicate with Howard B. Sprague, M.D., 1180 Beacon Street, Brookline, Massachusetts (telephone ASpinwall 7-1550), representing the New England Heart Association.

Fourth-year students in approved medical schools are reminded of the *Journal's* prize-essay competition on preventive medicine.

For further information see *The New England Journal of Medicine*, September 30, 1948, p. 525, or write to the editor.

MASSACHUSETTS MEDICAL SOCIETY

DEATHS

GALLAGHER — John V. Gallagher, of Milford, died on September 17. He was in his seventy-second year.

Dr. Gallagher received his degree from Tufts College Medical School in 1902. He was medical examiner of the Sixth Worcester District and was a member of the staff of Milford Hospital.

His widow, a daughter and a son survive.

SHERBURNE — Andrew E. Sherburne, M.D., of Portsmouth, New Hampshire, died on January 29. He was in his seventy-sixth year.

Dr. Sherburne received his degree from Harvard Medical School in 1903.

His widow, two sons and five grandchildren survive.

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

COMMUNICABLE DISEASES IN MASSACHUSETTS FOR JANUARY, 1949

RÉSUMÉ

DISEASE	JANUARY 1949	JANUARY 1948	SEVEN YEAR MEDIAN
Chancroid	10	2	2*
Chicken pox	4155	2322	2274

Typhoid fever	0	2	2
Undulant fever	3	2	2
Whooping cough	304	454	612

*Five-year median

COMMENT

Diseases with incidence higher than the seven-year median were chicken pox, diphtheria, German measles, measles, mumps and undulant fever.

Diseases with incidence lower than the seven-year median were scarlet fever and whooping cough.

Chicken pox was highest for any January since reporting began.

Measles had a higher incidence twice before — in 1926 and 1934 — than for this January.

Scarlet fever is steadily increasing in prevalence and will probably be exceeding the median within the next few months.

GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Diphtheria was reported from Arlington, 1, Boston, 24, East Brookfield, 1, Lynn, 2, Medford, 3, Revere, 1, Somerville, 1, Watertown, 1, Winchester, 1, total, 35.

Dysentery, bacillary, was reported from Worcester, 1, total, 1.

Encephalitis, infectious, was reported from Brimfield, 1, Lunenburg, 1, Springfield, 1, total, 3.

Lymphocytic choriomeningitis was reported from Fall River, 1, Fitchburg, 1, total, 2.

Meningitis, meningococcal, was reported from Boston, 1, New Bedford, 1, Rowley, 1, Salem, 1, Wakefield, 1, Westfield, 1, total, 6.

Meningitis, Pfeiffer-bacillus, was reported from Lawrence, 1, New Bedford, 1, Springfield, 1, West Brookfield, 1, Westfield, 1, total, 5.

Meningitis, pneumococcal, was reported from Haverhill, 1, Tewksbury, 1, Weymouth, 1, total, 3.

Meningitis, undetermined, was reported from Adams, 1, Bedford, 1, Haverhill, 1, North Adams, 1, Pembroke, 1, total, 5.

Salmonellosis was reported from Boston, 2, New Bedford, 1, total, 3.

Septic sore throat was reported from Boston, 5, total, 5.

Tetanus was reported from Deerfield, 1, total, 1.

Trichinosis was reported from Fall River, 1, Mansfield, 1, Northampton, 1, Weymouth, 1, total, 4.

Tularemia was reported from Tisbury, 1, total, 1.

Undulant fever was reported from Marblehead, 1, Rutland, 1, Westboro, 1, total, 3.

MISCELLANY

VFW CRAVE CHIROPRACTIC

Bill 1512, introduced into the House of Representatives by Representative Walter B. Huber, Democrat, of Ohio, authorizes the appointment of chiropractors in the medical department of Veterans Administration, according to Washington Report on the Medical Sciences. The measure, similar to one sponsored last year by Representative Patterson of Connecticut, was filed at the request of Veterans of Foreign Wars.

Are not the veterans sticking their necks out in asking Government to pay to have them broken for them?

CORRESPONDENCE

OPPORTUNITIES IN THE NATIONAL GUARD

To the Editor I wish to take this opportunity of presenting to the physicians in the Greater Boston area, especially house officers and younger veterans of World War II, the desirability of joining the Massachusetts National Guard and more particularly the 114th Medical Battalion of the 26th Division, which I have the privilege of commanding. This organization is charged with second-echelon evacuation, triage, emergency surgery and early psychiatric therapy in combat. In peace we are training to accomplish these missions and in addition to be prepared to be of service in event of major civil disaster. Working in co-operation with civilian agencies, we as an organization are prepared to co-ordinate ambulance runs and to serve as an office of record for casualties, we have the facilities to set up quickly and efficiently a collecting station for treating, sorting and clearing casualties. Thus, a medical officer in this organization has the dual opportunity of preparing himself to serve usefully in time of war and to be of service to his community in the event of disaster.

There are other advantages of a more immediate character—namely, good fellowship in a slightly different atmosphere than usually exists in a physician's daily life, pay for two hours' work a week, and full pay and allowances for two weeks on Cape Cod in the summer. Since the passage of a civilian component retirement act by Congress last summer, service in the National Guard is the quickest and easiest way to earn the required points for a retiree's income at age sixty. Where else in the world can one set up an annuity and get paid for doing it?

Since the war, the 26th Division has been almost entirely reorganized. In the Medical Battalion all administrative duties are carried out by nonmedical personnel, so that no physician is required to take property responsibility, or worry about rosters, payrolls and the like. This is a much happier situation than many of the junior medical officers of the last war had. It assures a physician that he will be doing professional work only. I have vacancies for majors, captains and lieutenants—medical corps. Any physician who gained the rank of major, or its Navy equivalent, during the war or on a terminal leave promotion is eligible for the same rank in the 114th Medical Battalion. Any house officer or recent graduate without previous military service may obtain a commission as first lieutenant. A physician's status in any other civilian component of the armed services is not jeopardized, since, though it is necessary to vacate a reserve commission to accept one in the National Guard, a physician may resign at any time and revert to his previous status without prejudice or loss of seniority.

Medical students may also be of use to us in the ranks and may augment their incomes with the pay of the grade for which they qualify. There are numerous noncommissioned officer vacancies, which I will be happy to fill with qualified medical students. By enlisting in the 114th Medical Battalion, a medical student may not only earn a few extra dollars a week but also become familiar with the work of the Army Medical Department and become eligible immediately upon graduation for a commission as first lieutenant Medical Corps. The work is interesting, useful and not too arduous or time consuming and pays. We drill on Thursday nights at the South Armory, Irvington Street, Boston. I may be reached by telephone during the week at Commonwealth 6-5142.

DONALD T. CHAMBERLIN, COLONEL MC
Massachusetts National Guard

Boston

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

What Is Psychoanalysis? By Ernest Jones, M.D. 8°, cloth, 126 pp. New York: International Universities Press, 1948. \$2.00.

Dr. Jones, a recognized English authority on psychoanalysis, first drafted this small book in 1928. The author states that in this second edition he finds little that needs changing. In a short addendum he discusses briefly the modern trends and problems of psychoanalysis.

Correlative Neuroanatomy By Joseph J. McDonald, M.S., M.Sc.D., M.D., Joseph G. Chusid, A.B., M.D., and Jack Dange, M.S., M.D. 8°, cloth, 156 pp., with 60 illustrations. Fourth edition. Palo Alto, California: University Medical Publishers, 1948. \$3.00.

This students' manual was first published in 1938. It covers gross anatomy, neuroanatomy, neurodiagnosis and neurology and correlates anatomy and physiology with the clinical findings of diseases of the nervous system. The text is divided into three parts: the peripheral nerves, neurodiagnosis, and diseases of the central nervous system. An appendix gives a complete list of neurologic signs and symptoms, a brief discussion of muscular dystrophies and atrophies and an outline of the neurologic examination. A good index concludes the volume. The printing is done by a reproductive process. The outline illustrations are good and clear. The binding is of the ring type, common to students' notebooks.

Bright's Disease By Henry A. Christian, A.M., M.D., LL.D., Sc.D. (Hon.), M.A.C.P., Hon. F.R.C.P. (Can.), D.S.M. (Am. Med. Assoc.). Reprinted from *Oxford Loose-Leaf Medicine* with the same pagination. 8°, cloth, 384 pp., with 40 illustrations and 38 tables. New York: Oxford University Press, 1948. \$9.00.

This monograph brings the subject up to date and reflects the author's experience of forty-seven years in the study of kidney diseases, and presents his concept of the disease. The classification is the clinical one devised by Dr. Christian. A bibliography of 492 references concludes the text. There is a good index. The reprint of this important contribution makes it available to persons not having access to the loose-leaf system. The type, paper, printing and illustrations are excellent. The price is high but is probably justified by the complicated tables, charts and illustrations.

NOTICES

ANNOUNCEMENT

Dr. Henry H. Lerner announces the opening of his office for the practice of roentgenology at Physicians Hall, 314 Commonwealth Avenue, Boston.

HARVARD MEDICAL SOCIETY

A meeting of the Harvard Medical Society will be held in the amphitheater of Building D, Harvard Medical School, on Tuesday, March 8, at 8 p.m. The chairman for the evening will be Dr. George W. Thorn.

PROGRAM

The Use of Fraction I for Separation of Erythrocytes and Leukocytes from Whole Blood. Edward S. Buckley, Jr., Marvin J. Powell and John G. Gibson, II.
The Role of the Hypothalamus in the Adrenal Cortical Response to Stress. David Hume, Peter H. Forsham and George Whittenstein.

Pulmonary Hypertension Lewis Dexter, Eugene Eppinger, James Whittenberger, Florence W Haynes, Harper K Hellem, James Dow, Benjamin Ferris and Walter Goodale

Effect of Sulfanilamide on Salt and Water Retention in Congestive Heart Failure William B Schwartz, Jr

The Measurement of the Exchangeable Potassium by Isotope Dilution Leslie Corsa, Richard Steenburg, Margaret Ball and Francis D Moore

Use of an Artificial Kidney John P Merrill, Edmund J Callahan, III, and George W Thorn

Subsequent meetings will be held on April 12 and May 10

NEW ENGLAND SOCIETY OF ANESTHESIOLOGISTS

A meeting of the New England Society of Anesthesiologists will be held in the Auditorium of Building A, Boston University School of Medicine, 80 East Concord Street, Boston, on Tuesday, March 8, at 8 00 p m The scientific program will be as follows

Pain Problems in the Paraplegic Patient David P Crowell, M D

Technic and Anatomic Considerations of Stellate-Ganglion Block Edward J Twigg, M D

Reflex Sympathetic Dystrophy and Differential Spinal Block as a Diagnostic Aid Ruth M Anderson, M D

Physicians and medical students are invited

SOUTH END MEDICAL CLUB

The next luncheon meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, March 15, at 12 noon Dr Nathan Sidel will speak on the subject "Arthritis in General Practice"

Physicians are cordially invited to attend

AMERICAN ASSOCIATION OF INDUSTRIAL PHYSICIANS AND SURGEONS

The Industrial Physicians and Surgeons of the United States and Canada will hold their thirty-fourth annual meeting at Detroit, Michigan, April 2 to 9, with headquarters at the Book-Cadillac and Statler hotels Participating groups are the American Conference of Governmental Industrial Hygienists, the American Industrial Hygiene Association, the American Association of Industrial Dentists and the American Association of Industrial Nurses

EXAMINATIONS FOR APPOINTMENT IN NAVY MEDICAL CORPS

Examinations for the selection of candidates for appointment to the grade of lieutenant (junior grade) in the Medical Corps of the Navy will be conducted at all Navy hospitals in continental United States during the period April 4-8, 1949

Graduates of approved medical schools in the United States or Canada who have completed intern training in accredited hospitals or who will complete such training within four months of the date of the examination, and who are physically and otherwise qualified, may be examined for appointment as lieutenant (junior grade) in the Navy Medical Corps Candidates must be less than thirty-two years of age at the time of appointment.

Candidates will be required to appear before boards of medical examiners and supervisory Navy examining boards at the Navy hospital nearest their place of residence to demonstrate their physical and professional qualifications for appointment Following approval by the President of the United States and confirmation by the Senate, selected candidates will be issued appointment and orders assigning them to duty in a Navy medical facility for active service

As a result of the authorized additional compensation of \$100 a month for medical officers, a lieutenant (junior grade) in the Navy Medical Corps receives pay and allowances totaling \$5,011 a year if married, and \$4,575 50 if without dependents

Detailed information concerning the form and procedure of application may be obtained from the nearest Navy Officer Procurement office or from the Bureau of Medicine and Surgery, Navy Department, Washington 25, D C (Attn Code-3424)

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY, INC

The general oral and pathology examination (Part II) for all candidates will be conducted at Chicago, Illinois, by the entire Board from Sunday, May 8, through Saturday, May 14, 1949 The Hotel Shoreland in Chicago will be the headquarters for the Board Formal notice of the exact time of each candidate's examination will be sent him several weeks in advance of the examination dates Hotel reservations may be made by writing direct to the Shoreland

Candidates for re-examination in Part II must make written application to the Secretary's office not later than April 1, 1949

Candidates in military or naval service are requested to keep the Secretary's office informed of any change in address.

Applications are now being received for the 1950 examinations Application forms and Bulletins are sent upon request made to the American Board of Obstetrics and Gynecology, Inc, 1015 Highland Building, Pittsburgh 6, Pennsylvania

MANAGEMENT OF THE POTENTIALLY INFECTED OBSTETRIC CASE*

EDWARD G. WATERS, M.D.†

JERSEY CITY, NEW JERSEY

THE problem of potential infection in obstetrics is not new. Adam was the first man to attend a patient with potential infection in childbirth, and threat of infection is still the obstetrician's thankless heritage. Sepsis, which has been the leading cause of childbed death through incalculable ages, was uncontrolled until the first glimmering hopes were stirred by Alexander Gordon, Oliver Wendell Holmes, Charles White, of Manchester, and Ignaz Semmelweis.

When one considers the seemingly heroic efforts now required to reduce death rates by even 1 per cent, it is awesome to contemplate how the application of the simple principles enunciated by those pioneers lowered from 15 to 1 per cent the parturient death loss from sepsis alone. And this was before the revelations of Pasteur in 1879 established the groundwork, or the procedures of Lister became accepted and effective.

Today, many years later, puerperal sepsis still ranks among the most frequent causes of maternal death, despite the dangerously complacent attitude induced by the advent of the sulfonamides and antibiotic therapy. Although infection may be caused by any organism, four out of five are due to streptococci, and the most severe of these are the exogenous infections. The most frequent offenders, however, are the various nonhemolytic and some of the anaerobic streptococci, whose acquisition and acceleration of pathogenicity is dependent upon bacterial synergism in the presence of trauma, systemic disease, blood loss and other factors conducive to tissue destruction. The most dramatic and earliest reduction in patient loss came with control of exogenous infections. Cleanliness of the building, the bed and bedding, adequate ventilation, patient segregation, isolation of febrile patients, separation of personnel with or exposed to infections, adequate masking, surgical cleanliness of the obstetrician and aseptic vaginal examinations accounted for most of the improvement,

and these practices are still in effect. The persistence of puerperal fevers in spite of these precautions has led to an appreciation of the role played by endogenous infection and the manner in which organisms, in the presence of favoring conditions, assume degrees of pathogenicity that can be neither predicted nor calculated. Every post-partum and post-abortion patient has an open wound in the placental site. Most of the endogenous organisms not only are slow invaders but also break through the primary and local defenses with difficulty. The physiologic wound is well constructed by nature for its own protection. But lacerations, contusions and hematomas of the birth tract, retained secundines, blood loss, systemic disease and toxemia permit bacterial conversion to pathogenic status.

It is difficult to overestimate the enormous protection given the patient and the solace given the surgeon by the capacity of the sulfonamides, streptomycin and penicillin for control of infection. Deaths due to bacteremia from *Staphylococcus aureus* and *Streptococcus haemolyticus* have been practically eliminated in my experience. Without minimizing the beneficial effects of these substances, one must maintain a rational attitude toward present accomplishments. Chemotherapeutic attack is not sufficient for many of the infecting agents encountered. In many cases successful therapy is due to the maintenance of long and well established means for restoring physiologic balance in the patient under bacterial attack. In certain experimental work on peritonitis, also borne out by clinical observations, chemotherapy and the antibiotics are insufficient in themselves, once the disease is well established, to determine recovery. Survival is dependent upon the factors present before the onset of the disease or subsequent establishment of supportive measures to maintain the integrity of liver function, which is measurable by the capacity of the liver for normal prothrombin and fibrinogen production, requiring an adequate intake of protein and, through the avoidance of anoxemia, blood loss, hypotension and the like, a continuous supply of oxygenated blood. In any discussion of potential and actual infection

*Presented at the New England Postgraduate Assembly, Boston, Massachusetts, November 4, 1948.

†Assistant clinical professor of obstetrics and gynecology, Columbia University College of Physicians and Surgeons, New York City; division chief of obstetrics, Margaret Hague Maternity Hospital.

during labor and consideration of the ultimate consequences therein implied, the two shock-producing factors of trauma and infection are almost always concomitant. This association, in addition to blood loss, with the inevitable lack of available oxygen for the maintenance of basic tissue and organ metabolism makes for one of the most severe combinations imaginable. Acute and spreading peritonitis in itself is productive of a severe and most intractable form of shock. While all forms of infection in association with trauma and blood loss are harmful, peritoneal-cavity involvement is by all odds the worst. Thus the combination found in a traumatizing delivery worsens the patient's prospects if the peritoneal cavity need be opened and exposed to direct infection. In the occurrence of peritonitis, the bacterial endotoxins manifest powerful shock-producing properties in their poisons. Certainly, one may assume, on the basis of practical experience in the exhibition of chemotherapeutic agents in combating peritonitis, that these drugs act favorably against bacteria and endotoxins by affording a nonspecific protective action in the patient treated but are often ineffective against overwhelming infection. The vascular poisoning with resultant blood concentration and plasma loss produces septic shock and accounts for the well recognized efficacy of repeated blood transfusions in peritonitis. It hardly seems necessary to repeat that it is more important to *prevent* infection than to have to *treat* it and more important to *avoid* peritonitis than to hope to *check* it after its development. Whether infections in labor are handled by vaginal or abdominal operative procedures, the occurrence of trauma, blood loss and infection (which, alone and in combination, cause shock) interferes with the amount of oxygenated blood specifically needed for the organs and tissues for the maintenance of normal physiology. Hepatic function within physiologic range above all others must be maintained.

Infection during labor and the puerperium must therefore be regarded as wholly preventable if the patient is to be given maximal protection. This assumption is not invariably correct but must be so accepted to approach the irreducible minimum of patient loss.

Accordingly, I have included in management of infected labor some brief reference to the antecedent pregnancy, influencing factors in the labor, the preferential selection of manipulations for delivering the infected patient, and, finally, prevention of infection in the post-partum phase.

DURING PREGNANCY

It would be short-sighted indeed to regard obstetric infection as solely dependent upon omissions or commissions during labor and parturition. During the pregnancy itself, the obstetrician should prevent infection by lessening its occurrence and

minimizing its effects when it does occur. Without discussing this phase of the subject exhaustively, one may comment on some of the more obvious measures that can be taken. The patient's general nutrition, especially vitamin and protein balance, should be maintained throughout pregnancy, and especially in the last trimester. The blood picture must be known for the physician to detect and correct any existing anemia. Patients are routinely checked for Rh and blood type, and the record is made available on hospital admission. Early detection and treatment of cervicitis, pyelocystitis, vaginal infections and the like, as well as a search for signs of early toxemia, diabetes and systemic disease, any of which may undermine the patient's resistance, are part of good patient care.

During the last six weeks of pregnancy, control of vaginal infection includes prohibiting tub baths, intercourse and douching, and consideration of intravaginal application of sulfonamides in the presence of active vaginal infection. In the last part of pregnancy all primiparas in whom the head is unengaged at term are examined by x-ray to guide the obstetrician in his later management. All multiparas with histories of previous difficult deliveries should be scrutinized and given most careful x-ray study. It is important with the latter group to inquire exhaustively into the causes of previous stillbirths and neonatal deaths, which may offer a clue to prevention of recurrent fetal death or even greater catastrophe.

DURING LABOR

It is during labor that opportunities become most manifest and operative in determining the development of infection as well as the type of delivery. Repeated vaginal examinations, especially when there is a low placental implantation and when the membranes have been ruptured, are notable for increasing morbidity. Likewise, rectal examinations are not without danger inasmuch as adequacy involves protrusion of the rectovaginal septum by the examining finger through the cervix and against the presenting part. While in general it may truly be said that rectal examinations are preferable for routine checks during labor, there is no substitute in obstructive labor for a careful and complete vaginal examination done under aseptic precautions. This procedure will often completely reorient the operator and indicate a prompt decision on management. Abnormal positions and presentations can be most clearly made out, and these are prime factors in delayed labor with inherent septic possibilities. On this score, it should be noted well that disproportion and uterine inertia are almost inseparable and the presence of the latter bespeaks the existence of the former. This leads to prolonged labor, which, with or without ruptured membranes, means marked increase in morbidity and sepsis. Delayed labor due to midpelvic contraction is worse

than inlet contraction in that the condition is more easily overlooked, with a resultant longer labor. Failure of the head to engage or descend through the inlet is easily recognizable. In funnel-type pelvis, the obstetrician is often misled by early engagement, molding and a seemingly progressive although slow descent toward the pelvic floor. By the time he is aware of the true situation the life of the baby is often jeopardized, and he is put to it in deciding for the mother the safest means of ending labor.

When a patient has been in labor more than twelve hours or if the membranes without labor have been ruptured more than eighteen hours, it is my custom to start chemotherapy and antibiotic medication. Penicillin is most frequently used although often in combination with the sulfonamides, 40,000 units of penicillin is given initially, 300,000 units of procaine penicillin is given every twenty-four hours, and the dosage is maintained through the post-partum stage, being increased when indicated. Special regard must be given patients suffering from toxemia, chronic anemia or diabetes or who have lost blood from placenta previa or placental separation. The attendants are properly garbed and masked to control contamination. It has been estimated that 1 to 2 per cent of all patients are streptococcus carriers, and a higher percentage of the staff members are. Therefore precautions and preventive measures must be taken while the patient is in labor to obviate the likelihood of contamination. The treatment consists in overcoming any anemia that is present, replacement of blood that is being lost, treatment of any existing toxemia, assurance of sufficient fluid intake during labor, administration of adequate sedation to lessen the likelihood of too early interference in labor and strict observation of all of the standard obstetric principles. It is amazing, upon investigation for etiologic factors responsible for septic labor, how often such simple cardinal requirements for delivery as early appreciation of malpresentation and full dilatation of the cervix have been disregarded.

DURING PARTURITION

It follows when most of the foregoing precautions have been taken that infection in labor will not be a common sequel. However, in spite of this or because of some breach in judgment or management, the infected patient reaches the time when delivery is imminent or must be concluded. There can be little doubt that normal vaginal delivery is safest and best for both potentially and actually infected patients, since there is neither a sharp demarcation between the two nor any consistently positive method for indicating the transition from one to the other. Puerperal infection implies septic contamination of a wounded genital tract during labor or in the puerperium. Certainly, the normal transit

of a fetus through an undamaged birth tract ranks first in safety.

It should be remembered that cervical cultures from infected and normal patients do not differ significantly in bacterial content. Only when there is an overwhelming preponderance in the cervical or uterine culture of an organism found in the blood may it be considered significant. Some factor other than the mere presence of these endogenous infectors must be found to induce acquisition of virulence. The most important cause is trauma in a wide sense. The physiologic trauma induced by the separation of the placenta opens a large site for bacterial invasion. Except for contaminant organisms, the placental site is relatively well protected by nature against infection. A notable infector is the alpha-hemolytic streptococcus, for it is never endogenous and causes the worst infections (but it is most sensitive to chemotherapy). When one moves in any direction from normal vaginal delivery without trauma one increases the risk of puerperal sepsis. A close contender for safety to normal vaginal delivery is one accomplished by outlet forceps and perineotomy without other trauma. In what has been said thus far, there seems to be some concordance of opinion even among those who do battle over preferable ways for abdominal delivery.

Difficult forceps extractions are probably the greatest contributors to maternal deaths from sepsis. I do not mean that there is no place in obstetrics for mid-forceps deliveries or, for that matter, craniotomies on dead babies. I have indicated that mid-forceps in the presence of mid-pelvic contraction or funnel-type pelvis is dangerous and should be supplanted by better means for delivery. I believe their frequent use will disappear with widening indications for cesarean section and with more conservative treatment of the second stage of labor. Many of these patients with adequate sedation, general supportive treatment and judicious use of small doses of pitocin would deliver spontaneously if given enough time. Patients with adequate pelvis with dystocia due to malpresentation and deflection attitudes can be delivered by various means, and I prefer Kielland forceps rotation and extraction in many of these cases. The effectiveness of a mid-forceps application depends upon the degree of cephalic flexion present and the ability of the operator, in the absence of mid-pelvic contraction, to exert traction without deflection of the head. Better results from mid-forceps application will follow their disuse in patients with mid-pelvic and outlet contractions, and selective adoption of the proper forceps for the given pelvis and the special position of the vertex therein to be engaged. But the most important consideration of all, in the absence of definite dystocia, is reliance upon sedation and time. To put the matter in other words, one might say that no potentially or actually infected patient

should have a traumatizing vaginal delivery if the incidence of puerperal sepsis is to be diminished. If abdominal delivery is indicated, as often it must be by the very nature of the circumstances resulting in infected labor, there are two broad selections available. The first is cesarean section by one of the several types, and the second is cesarean section followed by hysterectomy, which is briefly discussed below, that there may be no mistake in my position.

Cesarean hysterectomy is not atraumatic. If the infected uterus is opened for the removal of the baby before it is extirpated, the result is not much better than that from a classic cesarean section. If a Porro type of operation is done, the baby's life is jeopardized. In any event a transperitoneal operation is performed, and the infected birth tract cut across, as indeed it must be, to remove the infected uterus. Sutures must then be placed

TABLE 1 *Total Mortality, January 1, 1938, to January 1, 1948*

DATUM	No	PERCENTAGE
Total deliveries	67,959	—
Total deaths	120	0.17
Total cesarean sections	2,287	3.30
Deaths after cesarean section	17	0.74

through infected tissue at the vault after an appreciable amount of intraperitoneal tissue has been traumatized and exposed at least to local infection. I am not without experience with this procedure and consider myself capable of estimating its extent, although I do not perform it for infected patients. Indeed, publications dealing with morbidity and mortality of cesarean section and hysterectomy relate in the vast majority of cases to noninfected patients, although the data might erroneously suggest operations done for true puerperal infection. It seems, therefore, that the salutary effect of this operation is removal of a part of the infected genital tract, most notably the uterine placental site with its possible postoperative infection. In opposition are the dangers of a transperitoneal operation, often with incision into the infected uterus before extirpation and always with an incision across and through the infected birth tract. The almost universal acceptance that normal, nontraumatic vaginal delivery is the best way to deliver potentially and actually infected women certainly seems to negate the need for removing the uterus itself. If figures can be presented, as I believe they can, to show that abdominal delivery with retention of the uterus and without invasion of the peritoneal cavity is as safe as or safer than cesarean section combined with hysterectomy for infected patients, there should be little dispute about how these patients should be handled. All obstetricians, especially teachers of undergraduate obstetrics, should

become so thoroughly adept at all the procedure, available that none of them would have to rationalize himself into the untenable position of chronically defending one type of procedure. With competence in all, judicious selection for the individual need will naturally follow, rather than autocratic pedantry exhibited by a one-operation department head.

Classic cesarean section was done for years for infection and obstruction in labor, with the ghastly results well known to everyone. The classic operation served its purpose and is respected for what it did when nothing better was available. It should never be done in infected labor and, in general practice, should never be done at all, except, for instance, as part of a cesarean section and hysterectomy for accompanying fibroids following clean labor with the patient at the end of her childbearing years. I believe the latter procedure is badly abused in young women with one or two children whose asymptomatic fibroids might better be treated later, if at all, by myomectomy. My experience with a large group of patients reveals the occurrence of fibroids in association with pregnancy as a rare indication for abdominal delivery. Excluding the irreconcilables, classic cesarean section should be considered as outmoded as vaccine therapy for pneumonia. Most obstetricians are in accord with the use of low-segment operations, especially with the transverse incision, for most patients coming to cesarean section. The question has recently arisen whether this operation with chemotherapy and the antibiotics is sufficient for patients who are potentially or actually infected. This will not easily or quickly be answered, and series offered with low mortality figures, of themselves, will not

TABLE 2 *Selective Data on Mortality, October, 1931, to January 1, 1945*

DATUM	No	PERCENTAGE
Total deliveries	75,238	—
Maternal deaths	200	0.26
Total cesarean sections	2,039	2.70
Deaths after cesarean section	29	1.42

suffice. It will take an accumulation of many deaths from puerperal infection and peritonitis following cesarean section with determination of the causes of the deaths and the technics of the operations to give the right answer. But at least it seems reasonable to believe that the transperitoneal approach cannot possibly be as safe as the extraperitoneal section, inasmuch as patients even now are dying from peritonitis in spite of adequate amounts of all the semispecific drugs available. Only when therapeutic measures available will save all patients who have peritonitis from dying, irrespective of the organism present, can one safely invade the peritoneal cavity to open

infected viscera, including the uterus. That day has not, as yet, arrived.

The data on mortality are presented in Table 1 and 2, and the relation of deaths to types of cesarean section in Table 3. Extraperitoneal cesarean section affords the safest of all abdominal approaches to the infected uterus. In an experience with 501 cases, with 1 death, or a mortality of 0.2 per cent, clean, potentially infected and grossly infected patients have been dealt with. The death that occurred was preventable on a technical basis. Sepsis due to direct invasion of the lymphatics and blood vessels without peritonitis was not seen. In this experience, dealing with more than 67,959 deliveries in the past ten years, 21 deaths from puerperal sepsis and peritonitis have occurred. The position of sepsis in relation to hemorrhage, toxemia and heart disease is indicated in Table 4. The subject of extraperitoneal cesarean section has been dealt with so often in the past few years that there is no need to reiterate all that has been said, but I believe, in view of the data submitted, that the onus is upon those who will neglect to use the best

placenta is extremely important. The use of oxytocics may be supplemented by use of bimanual compression if bleeding continues, as suggested nearly one hundred years ago by Hamilton. In any event the uterus *must not be packed*. In our clinic the intra-uterine pack is almost never used, and in the few cases in which it was, the patients died. In reading

procedure indicated when there is existing or probable infection.

The matter of anesthesia in these patients is of importance, especially if there has been any shock-inducing blood loss. Blood loss during parturition is difficult to estimate, but my rule is to consider that the patient has lost one and a half times as much as the highest estimate given. In a recent case with ruptured uterus, 2750 cc. of whole blood was given in addition to plasma and other intravenous fluids, and yet twenty-four hours later the hemoglobin was 50 per cent. In any event, it is highly improbable that too much blood would be given these patients. The anoxemia associated with blood loss is furthered by any general anesthesia, and local anesthesia is generally not suitable in the presence of infection, 90 per cent of my patients are delivered with a low spinal anesthetic and *forced oxygen* is given the patient *during* and *subsequent* to the operation. All vomiting patients are lavaged before anesthesia is induced. All measures mentioned can be applied in any hospital, large or small.

Irrespective of the manner of terminating labor, the control of blood loss after delivery of the

maternal mortality reports one is struck by the recurring allegation variously phrased, "the situation became alarming, and it was decided to pack the uterus." There has been no death from hemorrhage, and no uterus has been packed in the last 25,000 deliveries in this clinic.

POST PARTUM

I have allowed a limited time for the post-partum phase, because respect for and adherence to the advice and principles thus far enunciated for pregnancy and parturition largely obviate the need of special concern after delivery. This does not minimize in any respect the great importance of the post-partum period in relation to infection. In the potentially and actually infected patient, irrespective of the manner of delivery, previously indicated therapy must be continued, and repeated checks made to obviate continuing or unrecognized secondary anemia. It is well to remember that careful inspection of the placenta will not eradicate occurrence of placental-remnant retention, with post-partum complications. Frequent offenders are small overlooked succenturiate lobes. Many deaths from puerperal fever follow nonfatal but severe hemorrhage in the post-partum period. Manipulations attendant upon its control, especially packing, and the debilitated state induced, permit the invasion and growth in virulence of organisms that normally would be inoperative. Late post-partum hemorrhages are generally severe and sudden and are due to incomplete separation of retained secundines or overlooked placental pieces. Bleeding, especially when accompanied by fever, signifies septic involvement of retained

should have a traumatizing vaginal delivery if the incidence of puerperal sepsis is to be diminished. If abdominal delivery is indicated, as often it must be by the very nature of the circumstances resulting in infected labor, there are two broad selections available. The first is cesarean section by one of the several types, and the second is cesarean section followed by hysterectomy, which is briefly discussed below, that there may be no mistake in my position.

Cesarean hysterectomy is not atraumatic. If the infected uterus is opened for the removal of the baby before it is extirpated, the result is not much better than that from a classic cesarean section. If a Porro type of operation is done, the baby's life is jeopardized. In any event a transperitoneal operation is performed, and the infected birth tract cut across, as indeed it must be, to remove the infected uterus. Sutures must then be placed

become so thoroughly adept at all the procedures available that none of them would have to rationalize himself into the untenable position of chronically defending one type of procedure. With competence in all, judicious selection for the individual need will naturally follow, rather than autocratic pedantry exhibited by a one-operation department head.

Classic cesarean section was done for years for infection and obstruction in labor, with the ghastly results well known to everyone. The classic operation served its purpose and is respected for what it did when nothing better was available. It should never be done in infected labor and, in general practice, should never be done at all, except, for instance, as part of a cesarean section and hysterectomy for accompanying fibroids following clean labor with the patient at the end of her childbearing years. I believe the latter procedure is badly abused in young women with one or two children whose asymptomatic fibroids might better be treated later, if at all, by myomectomy. My experience with a large group of patients reveals the occurrence of fibroids in association with pregnancy as a rare indication for abdominal delivery. Excluding the irreconcilables, classic cesarean section should be considered as outmoded as vaccine therapy for pneumonia. Most obstetricians are in accord with the use of low-segment operations, especially with the transverse incision, for most patients coming to cesarean section. The question has recently arisen whether this operation with chemotherapy and the antibiotics is sufficient for patients who are potentially or actually infected. This will not easily or quickly be answered, and series offered with low mortality figures, of themselves, will not

through infected tissue at the vault after an appreciable amount of intraperitoneal tissue has been traumatized and exposed to local infection. I am not without experience with this procedure and consider myself capable of estimating its extent, although I do not perform it for infected patients. Indeed, publications dealing with morbidity and mortality of cesarean section and hysterectomy relate in the vast majority of cases to noninfected patients, although the data might erroneously suggest operations done for true puerperal infection. It seems, therefore, that the salutary effect of this operation is removal of a part of the infected genital tract, most notably the uterine placental site with its possible postoperative infection. In opposition are the dangers of a transperitoneal operation, often with incision into the infected uterus before extirpation and always with an incision across and through the infected birth tract. The almost universal acceptance that normal, nontraumatic vaginal delivery is the best way to deliver potentially and actually infected women certainly seems to negate the need for removing the uterus itself. If figures can be presented, as I believe they can, to show that abdominal delivery with retention of the uterus and without invasion of the peritoneal cavity is as safe as or safer than cesarean section combined with hysterectomy for infected patients, there should be little dispute about how these patients should be handled. All obstetricians, especially teachers of undergraduate obstetrics, should

TABLE 2 Selective Data on Mortality, October, 1931, to January 1, 1945

suffice. It will take an accumulation of many deaths from puerperal infection and peritonitis following cesarean section with determination of the causes of the deaths and the technics of the operations to give the right answer. But at least it seems reasonable to believe that the transperitoneal approach cannot possibly be as safe as the extraperitoneal section, inasmuch as patients even now are dying from peritonitis in spite of adequate amounts of all the semispecific drugs available. Only when therapeutic measures available will save all patients who have peritonitis from dying, irrespective of the organism present, can one safely invade the peritoneal cavity to open

*Based on therapeutic record and review of New York Rheumatism Association.

in all patients. Most of the patients, in addition, presented a low-grade fever, a leukocytosis and a moderately severe anemia. Some also had subcutaneous nodules or some variety of tenosynovitis.

To exclude subclinical visceral complications, thorough laboratory data were obtained in all patients prior to therapy. The blood studies consisted of complete cell counts, estimation of the hemoglobin and sedimentation rate, determination of the nonprotein nitrogen, sugar, uric acid, total protein, albumin-globulin ratio, total cholesterol and cholesterol esters and icteric index and the cephalin flocculation test. Complete urinalyses were likewise performed. Renal-function studies consisted of the concentration and dilution tests and the phenol-sulfonephthalein excretion. Roentgenograms of the affected bones and joints were obtained in all cases. Joint measurements and the ranges of motion of the affected articulations were determined before and after therapy.

None of the patients treated gave a history of known toxicity to gold, though any evidence of impaired renal function or suffered from any blood

therapeutic measures for the prevention of deformity, was permitted.

While the patients were receiving aurotherapy, complete blood counts, including platelets, and urinalyses were performed twice weekly. The erythrocyte sedimentation rate was determined every two or three weeks.

Sixteen patients received lauron, 1 aurothio-glucose (solganol-B oleosum), and 1 gold sodium thiomalate (myochrysin) for comparative information.

The dosage of gold salts varied from 0.9 to 10 gm. The entire quantity was given intramuscularly, in divided, ascending doses twice weekly, for six to eight weeks. Eight patients received a total amount of 10 gm. during this period, 4 were given 3 gm., and the remainder, 0.9 to 1.2 gm. Each of the patients treated with solganol-B oleosum and myochrysin received 1 gm. of these respective gold salts. Several patients on intermediate total courses of lauron, and 1 on a 1-gm. course of gold sodium thiosulfate, have been excluded because they did not remain in the hospital long enough

placental segments. The blood must be replaced, Fowler's position employed to ensure adequate genital drainage, and the vaginal and perineal wounds inspected if morbidity persists. These patients are all given oxytocics, preferably ergotrate, routinely the first three days post partum to hasten involution and to close off venous and lymphatic channels of spread. Adequate fluid and vitamin intake is ensured, the bladder is kept empty, the blood picture is constantly checked, blood cultures and urine specimens are obtained if the fever continues and early ambulation is encouraged when the infection is under control. It should be recalled that increased trauma with tissue autolysis increases prothrombin formation and platelet production and thereby increases the possibility for peripheral and unfavorable clot for-

mation. The use of heparin and dicumarol, in sequence or independently, is indicated to check thrombus formation or spread.

CONCLUSIONS

Puerperal sepsis often has its beginnings in states and conditions during pregnancy that enhance its development. In the healthy patient going into labor, blood loss, toxemia and trauma, incident to or subsequent upon prolonged labor, inertia and difficult delivery, are the most important factors in its production. The treatment of infection or obstruction in labor demands individual consideration of all the possibilities in the patient's interest, normal, nontraumatic vaginal delivery and extra-peritoneal cesarean section offering, by all odds, the most favorable prospects.

INTENSIVE CHRYSOTHERAPY (WITH LAURON) IN RHEUMATOID ARTHRITIS*

H. HAROLD FRIEDMAN, M.D.,† AND OTTO STEINBROCKER, M.D.‡

NEW YORK CITY

THIS report presents the results obtained with intensive chrysotherapy in the treatment of 18 patients with rheumatoid arthritis. The purpose of the study was to investigate the usefulness of large quantities of gold salts administered over a relatively short period. In spite of the limited number of cases treated, our observations are reported for whatever significance they may have, since we do not plan to continue the investigation.

Although there has been a trend in this country toward relatively small doses of gold salts, intensive treatment with gold compounds was employed for several reasons. The manufacturer of the preparation used in this study proposed an investigation of the possibilities of intensive dosage under hospital conditions because a single dose of 5 gm. administered erroneously to a patient by her physician had resulted in some apparently rapid benefit and had not been attended by untoward reactions, because a short period of intensive treatment in a hospital, if found to be safe and practical, might be advantageous for patients unable to submit to the conventional long-term treatment, and because aurothioglycanilide (lauron), being insoluble and therefore more slowly absorbed, might provide, with intensive doses, a store of gold in the

body that would be released for a long period to maintain beneficial effects. The fact that large doses of gold salts had been regularly given and are still advocated by some European workers gave us some reassurance. Furthermore, we had used lauron for some time in small doses and found the frequency of toxicity, in a limited series of cases, to be no greater and generally milder than that of soluble gold preparations.

Although we had not been impressed with the final effectiveness of conventional doses of gold salts, the use of large doses, if found safe, appeared to be a worthy test of the efficacy of chrysotherapy, at least of lauron, in any suppressive action on the rheumatoid process or palliation of symptoms. It so happened that, at about the time we were contemplating this study, a patient with active rheumatoid arthritis, who had experienced a number of failures with other modes of therapy, volunteered in his desperation to undergo "any experiment that might help in the slightest way." He consented to the regime proposed, and his was the pilot study. Ten gm. of lauron was administered to him in ascending doses over an eight-week period without complication. His dosage schedule was followed in other patients who received this amount.

METHODS OF STUDY

Eighteen patients with active rheumatoid arthritis in various stages of the disease were selected for treatment. They were classified as presenting the early, moderately advanced or greatly advanced stage, according to the severity

*From the Medical Service and Arthritis Clinic of the Fourth Division (New York University) Bellevue Hospital.

This study was aided by a grant from the Endo Company which also supplied the material.

and showed slightly decreased signs of rheumatoid activity beginning four, five and six months respectively after completion of gold therapy in what again might be regarded as "delayed responses."

The toxic reactions in this series consisted only of one severe and one mild local exfoliative dermatitis. The patient with the severe exfoliative dermatitis, after a stormy course, made a complete recovery.

Eosinophilia of varying degree was encountered in nearly all these patients while they were under treatment. The count ranged from 3 per cent to 17 per cent in 15 of them. Two cases with eosinophil counts up to 22 per cent and 43 per cent developed, respectively, a mild and a severe exfoliative dermatitis. A high degree of eosinophilia may be a premonitory sign of impending toxicity, although one patient exhibited a count of 29 per

It may not be irrelevant to mention at this point that even the better results of the small doses are statistically close to those reported by Short and Bauer⁴ with simple medical and orthopedic measures. It is therefore doubtful whether aurothioglycanilide in either of these groups has shown promise of long-range benefits superior to those observed after general medical measures. However, a suggestively greater number of initial remissions following completion of chrysotherapy among patients receiving smaller doses can have been only of questionable significance in such a small number of patients for the length of time treated.

In our very limited series of cases, large doses of lauron did not prove unduly toxic, but it must be stated that one of us (O. S.) has observed elsewhere severe skin reactions from conventional doses of aurothioglycanilide. In fact, in our small series

cent without adverse symptoms. Further detailed experience with eosinophilia in chrysotherapy will be reported separately.³

DISCUSSION

From the results obtained in a limited series of cases, according to our standards of evaluation, it appears that intensive gold therapy with large or accelerated doses of lauron offers no advantage over treatment with smaller doses in the usual manner. The number of patients is admittedly too small to permit final appraisal of this form of treatment, although it does provide a highly suggestive index to its effectiveness. For comparison, we are including the results obtained by us with the usual doses of lauron in 20 patients with this disease (Table 3). In this group the total dosage ranged from 1 to 3 gm, given in one to three courses for six months to two and a half years, together with a follow-up period of from two and a half to four and a half years. If it is permissible to draw tentative deductions concerning the trend of response in such small groups, the figures suggest, surprisingly enough, that the immediate results with lesser doses are better than those with massive dosage.

all toxic reactions with usual and large doses of this substance consisted of cutaneous manifestations. An unpredictable personal factor probably is involved in many toxic reactions and fortunately did not appear, except in 1 case. This patient developed a severe exfoliative dermatitis. Since this complication may occur with small doses of gold, it cannot be ascribed merely to the large amounts employed.

On the whole the results obtained with intensive and accelerated chrysotherapy in this relatively small number of cases have been poorer than those reported by others with lauron⁵⁻⁷ and with other gold salts. Since aurothioglycanilide is an insoluble salt, the question then arises whether it is absorbed in sufficient quantities to be effective, particularly when given so rapidly and in massive doses. The fact is that the blood levels attained by the large doses of lauron, estimated by spectrography, were within the ranges of those produced by much smaller quantities of the other gold compounds, or they showed a rise in proportion to the amount of this salt administered (Table 4), at least one week after the completion of therapy. While it is true that roentgenograms taken by us, in some cases as long as two years after lauron therapy, have

for sufficient therapy. It was planned at first to treat a larger group given varying total courses evenly distributed among the series. The outcome of treatment at this point, however, led to the termination of the study. Maintenance doses were not employed afterward for obvious reasons.

Patients were included consecutively without any attempt at selection according to the severity of the disease, except for terminal cases. An explana-

tion was given. The 2 patients whose rheumatoid activity slightly decreased have maintained that improvement so far. Both have also shown marked improvement in functional capacity. Semi-invalids prior to treatment, both have subsequently been able to conduct their occupations satisfactorily in spite of persistent signs of rheumatoid activity.

One patient with early rheumatoid arthritis was unimproved after termination of her course of 10

†Classification of stages and grades (I—complete remission, II—major improvement, III—slight or minor improvement, and IV—no improvement) of response according to criteria of the New York Rheumatism Association. The response was re-evaluated from results on our therapeutic score card in some cases.

‡One patient had early disease in remission 3 months after completion and another had greatly advanced disease with complete remission 6 months after the end of treatment.

tion of the character of the treatment was given, after which each one was required to sign a permit.

RESULTS

The results obtained are given in Table 1 and 2. Evaluation of the response to treatment was carried out by means of the criteria provided in our therapeutic score card,² which, aside from a few minor differences, is in close accord with the therapeutic criteria adopted by the New York Rheumatism Association. Late in the study these therapeutic

criteria were applied simultaneously with the therapeutic score card. Three months later a widespread exfoliative dermatitis developed, and simultaneously there was a complete remission of the arthritic picture. It might be questioned whether this remission can be credited to gold therapy since it occurred so long after aurotherapy was completed. For thirteen months this patient so far has remained in complete remission, except for a moderately elevated erythrocyte sedimentation rate, 40 mm in 1 hour (Westergren method)—

TABLE 3 *Results in 20 Cases of Rheumatoid Arthritis Treated with the Usual Doses of Lauron*

STAGE OF DISEASE	NO OF CASES	INITIAL RESPONSE				FINAL EVALUATION*			
		GRADE I†	GRADE II†	GRADE III†	GRADE IV†	GRADE I†	GRADE II†	GRADE III†	GRADE IV†
Stage I (early)†	10	5	1	2	2	2	0	3	6
Stage II (moderately advanced)†	4	1	0	2	1	0	1	1	2
Stage III (severe)†	6	1	0	3	2	0	0	3	2
Totals	20	7	1	7	5	2	1	7	10

*The follow-up periods ranged from two to four and a half years (recently completed). Recurrences in Grade I shifted (noted in three to thirty six months). There were 3 toxic reactions, none of which were serious.

†The classification of stages and grades of response re-evaluated from results on our therapeutic score card to therapeutic criteria of the New York Rheumatism Association was the same as that outlined in Table 2.

criteria were applied simultaneously with the therapeutic score card.

Of the 18 patients observed, 1 with early rheumatoid arthritis was in complete remission at the end of the course of gold therapy. Two patients in the greatly advanced stage showed slight improvement in the signs of rheumatoid activity, and the remainder were unimproved or worse when treatment was terminated.

The patient in whom remission was observed relapsed one year later, and her disease process is

“greatly improved,” according to the new therapeutic criteria.

Another patient, who was unimproved after chrysotherapy, had a complete remission six months later. Her disease process has remained clinically inactive for twelve months. It is more debatable in this case whether the good effect can be attributed to the therapy as a “delayed response” postulated for this type of gold preparation.

Three patients who initially were unimproved developed somewhat better functional capacity

SUBTOTAL GASTRECTOMY OR VAGOTOMY FOR PEPTIC ULCERATIONS*

Early Results and Postoperative Symptoms

RICHARD WARREN, M.D.,† AND EDMUND C. MEADOWS, M.D.‡

WEST ROXBURY, MASSACHUSETTS

EVER since the operation of vagotomy has been used in the treatment of peptic ulcer numerous reports have appeared analyzing the early postoperative results. The first of these that has made a direct comparison between the results of this operation and of those of subtotal gastrectomy has been that of Allen.¹ He found good results in 85 per cent of the gastrectomy groups and 87 per cent of the vagotomy, fair results in 7 per cent and 6 per cent, and poor results in 8 per cent and 7 per cent of the two groups respectively. The postoperative mortality in the gastrectomy group was 2 per cent, in the vagotomy group it was zero. Allen concluded that the early and interim results from the operation of vagotomy showed that the number of patients who did not fare satisfactorily after operation was roughly the same as that in the subtotal gastrectomy group. He outlined clinical criteria for the use of the two operations to serve as a temporary guide until more information on these operations should be acquired. Although the follow-up period of our patients who have had vagotomy is still extremely short we have been tempted to make a similar comparison between the operations and to check our results against those of Allen and other observers in this field.²⁻⁶

REVIEW OF THE LITERATURE

Follow-up studies on gastric surgery⁷⁻¹¹ have logically divided unfavorable results into three categories: mortality, incidence of recurrent (stomal) ulcer and incidence of unfavorable side effects—that is, easy gastric filling, nausea and vomiting, food intolerance, dumping syndrome, failure to gain weight, poor appetite and anemia.

Mortality

Reported mortality rates following subtotal gastrectomy have fallen during recent years^{7-10, 12-13} to a level of 1 to 3 per cent. The chief cause of this mortality has been technical failure properly to manage closure of the duodenal stump.¹⁴ Careful management and operative technic should, therefore, enable this figure to approach zero.

The mortality following vagotomy has been calculated as 1.6 per cent from a total of 481 cases

(Table 1). The causes of these deaths are listed in Table 2. With the exception perhaps of the case of aspiration pneumonia, they have been sudden and unpredictable.

Recurrences

The incidence of stomal ulcer following high subtotal gastrectomy for duodenal ulcer is between

from a total of 427 cases (Table 3). In the cases reported as recurrences by Dragstedt and his associates¹⁵ the insulin test of Hollander, in which insulin hypoglycemia is used to provoke a vagus-mediated gastric secretion, showed the operations to have been technically incomplete. In the study of Walters et al.¹¹ and in ours this has not been uniformly true. In 2 cases from the composite group new gastric ulcers developed in the postoperative period, vagotomy having been done for duodenal ulcer. A possible explanation for such an occurrence has been offered.²⁵

shown the presence of radiopaque material in the soft parts, spectrographic analyses of gold in the blood and excreta during the course of treatment, and afterward, in some of the patients in this series have shown gold levels within proportionately lower but comparable therapeutic ranges reported with other gold preparations.^{8,9} Chemical studies of gold in blood, urine and feces also were carried out in almost every case. Owing to the uncertainty among members of the Toxicology Department, where the analyses were done, regarding the accuracy and reliability of these determinations, it was deemed advisable not to include them.*

SUMMARY AND CONCLUSIONS

The results of intensive and accelerated gold therapy in 18 patients with active rheumatoid arthritis in various stages of the disease are reported. Sixteen patients were treated with aurothioglycanilide (laurox), one with aurothioglucose (solganol-B oleosum) and another with gold sodium thiomalate (myochrysine). The dosage ranged from 0.9 to 10 gm administered over a period of six to eight weeks in each case.

The initial results, immediately after completion of the gold therapy, were as follows: complete remission of signs, 1 case; slight improvement, 2 cases; and no improvement, 15 cases. The patient who went into complete remission subsequently relapsed.

*Spectrographic and chemical analyses were conducted through the courtesy and interest of Drs. Alexander O. Gettler and Charles J. Umberger.

Complete remission of symptoms and signs occurred in 2 other patients three and six months respectively after intensive chrysotherapy, and each has maintained that status for thirteen months. These may be regarded as initial, "delayed responses, but may have been spontaneous."

The use of large doses of gold salts over a short period in this series of patients was not attended by an increased number of reactions, but the group is too small for any positive deductions regarding the safety of intensive chrysotherapy.

Large and accelerated doses of aurothioglycanilide in these cases did not exert impressive palliative or suppressive effects on the signs and symptoms of rheumatoid arthritis.

SUBTOTAL GASTRECTOMY OR VAGOTOMY FOR PEPTIC ULCERATIONS*

Early Results and Postoperative Symptoms

RICHARD WARREN, M.D.,† AND EDMUND C MEADOWS, M.D.‡

WEST ROXBURY, MASSACHUSETTS

EVER since the operation of vagotomy has been used in the treatment of peptic ulcer numerous reports have appeared analyzing the early postoperative results. The first of these that has made a direct comparison between the results of this operation and of those of subtotal gastrectomy has been that of Allen¹. He found good results in 85 per cent of the gastrectomy groups and 87 per cent of the vagotomy, fair results in 7 per cent and 6 per cent, and poor results in 8 per cent and 7 per cent of the two groups respectively. The postoperative mortality in the gastrectomy group was 2 per cent, in the vagotomy group it was zero. Allen concluded that the early and interim results from the operation of vagotomy showed that the number of patients who did not fare satisfactorily after operation was roughly the same as that in the subtotal gastrectomy group. He outlined clinical criteria for the use of the two operations to serve as a temporary guide until more information on these operations should be acquired. Although the follow-up period of our patients who have had vagotomy is still extremely short we have been tempted to make a similar comparison between the operations and to check our results against those of Allen and other observers in this field.²⁻⁶

REVIEW OF THE LITERATURE

Follow-up studies on gastric surgery⁷⁻¹¹ have logically divided unfavorable results into three categories: mortality, incidence of recurrent (stomal) ulcer and incidence of unfavorable side effects — that is, easy gastric filling, nausea and vomiting, food intolerance, dumping syndrome, failure to gain weight, poor appetite and anemia.

Mortality

Reported mortality rates following subtotal gastrectomy have fallen during recent years^{7, 10, 12, 13} to a level of 1 to 3 per cent. The chief cause of this mortality has been technical failure properly to manage closure of the duodenal stump.¹⁴ Careful management and operative technic should, therefore, enable this figure to approach zero.

The mortality following vagotomy has been calculated as 1.6 per cent from a total of 481 cases

(Table 1). The causes of these deaths are listed in Table 2. With the exception perhaps of the case of aspiration pneumonia, they have been sudden and unpredictable.

Recurrences

The incidence of stomal ulcer following high subtotal gastrectomy for duodenal ulcer is between

from a total of 427 cases (Table 3). In the cases reported as recurrences by Dragstedt and his associates¹⁵ the insulin test of Hollander, in which insulin hypoglycemia is used to provoke a vagus-mediated gastric secretion, showed the operations to have been technically incomplete. In the study of Walters et al.^{16, 17} and in ours this has not been uniformly true. In 2 cases from the composite group new gastric ulcers developed in the postoperative period, vagotomy having been done for duodenal ulcer. A possible explanation for such an occurrence has been offered.²⁵

Unfavorable Side Effects

The difficulty of evaluating unfavorable side effects following gastrectomy was shown by St John and his co-workers,¹¹ who stated that almost 20 per cent of people without ulcers have, according to their answers to a follow-up questionnaire, symptoms that would place them in an unsatis-

factory group Jordan⁹ found that 60 per cent of patients had gastrointestinal symptoms of some sort after gastric resection for duodenal ulcer. St John et al¹¹ stated that approximately half the unsatisfactory results were due to features other than recurrent ulceration. Allen and Welch⁷ noted persistent gastrointestinal symptoms in a third of the patients. The most frequent residual symptom was that of a "small stomach,"—that is, the inability to eat a full meal, and discomfort, gas or

syndrome in 5.6 per cent of 500 cases. Contrary to popular opinion, they found that the syndrome persisted in 21 of 24 cases, after periods of five to eight years.

Hypochromic anemia following subtotal gastrectomy occurs in between 5 per cent and 9 per cent of cases.²⁸ Macrocytic anemia is very rare.²⁹ Anemia is more common in women than men³⁰ and is relatively unresponsive to iron and liver therapy, being best relieved by vigorous dietary means.³¹

The most detailed analysis of the unfavorable side effects following vagotomy has been made by Grimson and his co-workers,³ who in a series of 57 cases reported uncomfortable gastric fullness in 40, gas pains in 38, trouble with swallowing in 21, temporary diarrhea in 20 and episodes of acute epigastric pain in 6. The authors report, on the other hand, that 50 of the 57 patients gained weight postoperatively, and 53 were able to pursue gainful employment. Moore^{4, 5} has reported that although some symptoms, usually fullness, were present in 56 per cent of his patients, 87 per cent were satisfied with the result of the operation. A composite summary of this review of the literature is given in Table 4. It has served as a baseline for this study.

nausea after eating. They found that more patients lost weight than gained, but that symptoms referable to this were unusual. The average weight loss was nearly twice as high in women as in men.

The dumping syndrome, or "dumping stomach," so named by Mix²⁶ in 1922, represents perhaps a more distressing side effect of gastrointestinal anastomosis than any other. Custer, Butt and Waugh²⁷ found typical features of this postprandial

Roxbury Veterans Hospital with peptic ulcer (Table 5). 120 operations were performed with the purpose of curing the ulcer (Table 6). Eighty-nine of these operations were subtotal gastrectomies, 28 were vagotomies, and 3 were gastroenterostomies.

The selection of patients for operation was based upon their failure to be controlled on medical therapy. Medical treatment was deemed to have failed if pain could not be alleviated in the hospital.

Moreover, if outside the hospital under normal environmental conditions, a patient repeatedly became uncontrollable in spite of proper dietary discipline, he was selected for operation. Other indications of failure of medical treatment were repeated massive hemorrhages in a young man or one or more massive hemorrhages in an older one, and pyloric obstruction of a cicatricial sort. In general, the older the patient, the more seriously we have regarded the symptoms of hemorrhage.²² It is in this group that we have adopted the policy of urgent operation if the hemorrhage persists or recurs.²³

The patient with low intelligence, compensation neurosis or emotional factors that make it impossible for him to follow a proper medical regime presents a special problem. Results here are relatively poor regardless of the treatment used. In our clinic we have been more prone to treat these patients by surgical than by medical methods. This attitude has been adopted for the following reasons. The readmission of such patients to the hospital is frequent. Their complaints, although often unconvincing, can never be put aside as inconsequential as long as an active ulcer is shown by x-ray examination. After operation, which removes or heals the ulcer, although the patient's previous social and economic existence is seldom improved

uncertainties produced by conflicting x-ray studies, such as whether the ulcer was on the gastric or duodenal side, whether there were unusual duodenal deformities and occasionally whether an ulcer was present at all, obviously poor mechanical situations resulting from ill advised previous surgical procedures, such as high anterior gastroenterostomy,

the fear of serious complications such as perforation and hemorrhage is diminished and a complex clinical picture simplified.

In the group of patients chosen for surgical procedures we made a further selection for the operation of vagotomy by considering all patients suitable for vagotomy who did not have the following contraindications:²⁵ recent massive hemorrhage in patients over forty-five years of age, or active bleeding at the time of operation at any age, diagnostic

operated upon during the first eighteen months of the two-year period. The length of the intervals between operation and examination varied between four and twenty-four months.

Age

Because of the manner of selecting the two groups of patients there was considerable disparity in their average age. The ages of the gastrectomy patients ranged from twenty-three to sixty-six years and

averaged forty-nine years and one month. Those of the vagotomy patients ranged from twenty-three to fifty-two years, with an average of thirty-four years.

Mortality

There were 3 deaths in the gastrectomy group. A subtotal gastrectomy for gastric ulcer was followed by death due to pneumonia and paralytic ileus. A second patient succumbed to retroperitoneal sepsis from a leakage from the duodenal

continuity of at least some of the fibers of the right vagus.

At this early date there have been no proved recurrent ulcerations among the 54 patients whom we have examined since subtotal gastrectomy. One of the patients experienced ulcer type of pain, but barium meal and gastroscopy showed no ulcer and the pain disappeared after reassurance. Three others had epigastric pain unlike the previous ulcer pain. After making this study we have heard that 1 of the 2 patients receiving subtotal gastrectomies who did not respond to our request for a follow-up interview is at another hospital with an anastomotic ulcer. Two patients from the vagotomy group, in addition to the 3 who had recurrent ulcer, had some mild epigastric pain, but gastrointestinal x-ray films showed no active ulceration.

*The average gain in weight was 7.9 pounds for patients receiving gastrectomy and 5 pounds for those receiving vagotomy. The average hemoglobin in the two groups was, respectively, 79 and 87.5 per cent.

stump. The third patient died of pneumonia after an emergency operation for bleeding gastric ulcer done in the presence of bilateral lobar pneumonia and portal hypertension. Although this patient is included in the calculation of the total mortality of 3.3 per cent after subtotal gastrectomy, such inclusion does not render this figure accurate for elective subtotal gastrectomy, which is 2 deaths in 89 cases, or 2.2 per cent. Although there were no postoperative deaths following vagotomy, there were 2 late deaths, 1 from periarteritis nodosa and the other from perforated recurrent ulcer.

Recurrent Ulcer

Among the 22 patients who underwent vagotomy 3 demonstrated peptic ulceration postoperatively: one, a persistent and reactivated duodenal ulcer, another, a recurrent duodenal ulcer after six months of relief, and a third, a fresh ulcer occurring in the stomach a few days after vagotomy for duodenal ulcer. Two of these patients showed absence of vagus function according to the generally accepted interpretation of the insulin test. In the third case an insulin test was not performed. One of these patients is now well after a gastric resection. Another had a thorough exploration of the esophagus from the root of the lung to the stomach to determine whether regenerated nerve fibers could be discovered. Although none could be found, he was again relieved for six months by the exploration alone but then returned with a perforated ulcer fourteen hours old and died rapidly in shock before suture could be done. Autopsy showed persistent

Unfavorable Side Effects

Table 7 summarizes the incidence of unfavorable side effects in the two groups. Pure gastrointestinal symptoms such as pain, vomiting and diarrhea tend to be more prominent in the vagotomy group. Other symptoms such as poor appetite, fatigue and dumping syndrome predominate in the gastrectomy group.

General Appraisal

An appraisal of the success of the two operations was made by consideration of both the patient's statement whether he was satisfied and the examiner's appraisal of that statement. In the sub-

TABLE 8 Summary of Unfavorable Side Effects in 11 Patients Who Had Vagotomy in Addition to Gastrointestinal Anastomosis, as Compared with 11 Patients Who Received Vagotomy Alone

†The average weight gain in this group was 0 pounds and the average hemoglobin 85 per cent.

total gastrectomy group 41 (75.9 per cent) of the 54 patients were enthusiastically satisfied with the results of the operation. No patient was dissatisfied. In the vagotomy group 15 (68.1 per cent) of the 22 patients were enthusiastically satisfied, and 2 were dissatisfied. The examiner's appraisal in the gastrectomy group was that 28 (51.8 per cent) of the 54 patients had an optimal result, whereas only 4 had poor results. In the vagotomy group,

similarly, 10 (45 ± per cent) of the 22 patients had an optimal result whereas 4 had poor results. It is significant that the poor results occurred predominantly in the patients who had vagotomy alone rather than vagotomy in addition to a gastroenteric stoma (Table 8).

DISCUSSION

It is recognized that because of the manner of their selection the comparison between the two groups here presented is not strictly valid. Some of the contrasting results are explicable on the basis of differences in age, which might explain the difference in employment status and fatigability, for instance.

Another point in which the two groups differ is the fact that 31 ± per cent of the patients in the gastrectomy group, whereas none in the vagotomy group, had gastric ulcers. We have not, however, found the incidence of unfavorable side effects to be less in patients who have had subtotal gastrectomy for gastric ulcer than in those having subtotal gastrectomy for duodenal ulcer (Table 9).

Certain impressions can, however, be drawn from the study. Mortality following vagotomy has been slightly lower than that following gastrectomy. The causes of the deaths that have followed vagotomy, on the other hand, have often been unpredictable. This has not been true of the deaths following subtotal gastrectomy. The early recurrence of ulcer following vagotomy has not been strikingly less frequent than that following subtotal gastrectomy. The unfavorable side effects that follow vagotomy are as frequent as those following gastrectomy. They are, however, more likely to be gastrointestinal—that is, vomiting and diarrhea. In the gastrectomy group, dumping syndrome, failure to gain weight and loss of energy predominated. The patients who had a vagotomy with a gastroenteric stoma gained, on an average, no weight. It may be that the addition of such a stoma to the operation of vagotomy prevents symptoms of gastric retention but adds the factor of interference with nutrition that may plague the patient after gastrectomy.

In general the results in our small group and the impressions drawn therefrom have coincided with those of Allen.¹ We have found a slightly higher incidence of ulceration after vagotomy (3 cases in 22) than he reported (1 case in 75). Our good results in both the vagotomy and gastrectomy groups are about 10 per cent lower than his. For the purposes of the over-all impression, however, these differences are minor.

We recognize that a patient who enjoys a perfect result after vagotomy possesses a gastroduodenal tract that is anatomically and functionally more nearly normal than that of a patient who has received a subtotal gastrectomy. We hope that a larger experience with the procedure will teach

us how to make such results the rule. Until that occurs, however, it seems to us wise that as a routine policy subtotal gastrectomy should be the preferred elective operation for most patients with duodenal and gastric ulcers. Vagotomy we now reserve for the patient with marginal ulcer or the patient who is young and in whom a strong emotional background to the hypersecretion can be established either by laboratory test or by surmise from the patient's reaction to his environment. When

†The average weight gain in this group was 9 pounds and the average hemoglobin 78 per cent.

vagotomy is performed for duodenal ulcer a concomitant gastroenteric stoma is created to avoid excessive gastric retention.

SUMMARY

An analysis is made of a series of 120 definitive operations performed for peptic ulcerations of the stomach, duodenum and gastroenteric stoma with a view to comparing the results following subtotal gastrectomy and those following vagotomy.

The mortality was 3.3 per cent among 89 subtotal gastrectomies and 0 among 28 vagotomies.

Fifty-four patients who had subtotal gastrectomy and 22 patients who had vagotomy were examined four to twenty-four months after operation. There was 1 early recurrence of peptic ulceration in the former group, and 3 in the latter.

We have confirmed the findings of Allen that the incidence of unfavorable side effects was quantitatively comparable in the two groups and have concluded with him that for the time being the use of vagotomy should be restricted to patients with anastomotic ulcer and to young patients without pyloric stenosis and with a presumably strong emotional phase of gastric secretion.

JOHN K. MENEELY, JR., M.D.†

ALBANY, NEW YORK

THE presence of cardiac murmurs as an aid in the diagnosis of subacute bacterial endocarditis has been stressed in the past. Paul et al.¹ noted significant murmurs on admission in 100 per cent of their 44 cases treated with penicillin. Levine² states that "the absence of any murmur is a very reliable clue in eliminating the diagnosis of subacute endocarditis" and comments that he has seen only one case in which no murmurs were heard. White,³ however, mentions the development of murmurs during the course of the disease, and indicates that in rare cases no murmurs are ever present. The following cases, 2 of subacute bacterial endocarditis and 1 of acute bacterial endo-

carditis, are reported to emphasize two points: the necessity of suspecting subacute bacterial endocarditis in all patients with fever even if they have no previous rheumatic history and are without cardiac murmurs at the time of initial examination, and the necessity of considering healed bacterial endocarditis as a cause, per se, of persistent cardiac murmurs.

CASE REPORTS

CASE 1 (A. H. 161167). A 42-year-old man entered the hospital with the chief complaint of headache and fever for 3 weeks prior to admission. The onset of this illness had been ushered in by a shaking chill. The past and family histories were noncontributory, no history of rheumatic fever could be elicited.

Physical examination was entirely within normal limits. No splenic enlargement or petechiae were noted, and there were no heart murmurs.

The temperature was 100.6°F, the pulse 80, and the respirations 20. The blood pressure was 120/62.

Laboratory examination revealed a moderate anemia and a slight leukocytosis. A chest film was negative. The Widal and brucella agglutination tests were also negative.

On the day after admission, two small resolving hemorrhages were noted in the left optic fundus. Six days later, small hemorrhages were noted in the right fundus. Five days later, petechiae were noted in both the right and the left conjunctiva, and on the right abdominal wall. Numerous blood cultures were taken and reported as negative, but 1 month after admission three blood cultures drawn on the day of admission were reported as positive for *Streptococcus viridans*. The patient received a total of 35,000,000 units of penicillin intramuscularly over a 5-week period. The temperature fell slowly to normal and remained so for 23 days before penicillin was discontinued.

It was not until 6 weeks after admission that a blowing, Grade III systolic murmur was noted over the precordium, loudest at the apex and transmitted to the axilla.

*Professor of medicine, Albany Medical College; head, Department of Medicine, Albany Hospital.

†Assistant in medicine, Albany Medical College; medical director, Albany Hospital.

The patient was discharged, well and without complaints, 3 months after admission.

When the patient was seen for follow-up study, 9 months later, a forceful, Grade III systolic murmur was still noted over the entire precordium, associated with an absent mitral second sound. The heart border was enlarged to the left.

CASE 2 (A. H. A67506). A 60-year-old man was admitted to the hospital with the chief complaint of hematuria of 4 months' duration. 10 months before the onset of the hematuria a right-sided hemiplegia had suddenly developed and persisted. There had been a 30-pound weight loss over the 1-month period.

The family history was noncontributory, and the patient history of significance only in that the patient "thought he had a heart murmur" as a child.

Physical examination on entry revealed a mild right hemiplegia, but the remainder of the physical examination was entirely negative. No petechiae were noted. The spleen was not enlarged, and no heart murmurs were heard by a careful observer.

The temperature was 101.1, the pulse 90, and the respirations 30. The blood pressure was 134/82.

Laboratory examination revealed 5 to 8 red cells per high-power field in the sediment, a rather marked hypochromic anemia and a slightly elevated nonprotein nitrogen.

On the 5th hospital day, it was noted that the aortic second sound was accentuated, and it was thought that a very soft systolic murmur was heard in this area. Six days after admission, a small retinal hemorrhage was noted in the left eye. Three days later the spleen was found to be enlarged. Two weeks after admission the aortic systolic murmur had become very loud, fresh subconjunctival petechiae were noted, and 10 petechiae were discovered in the buccal mucous membrane. A blood culture on this day was positive for *Streptococcus*. Penicillin, in a dose of 1,000,000 units intramuscularly daily, was begun and continued for 3 weeks, with a rapid fall in temperature. Subsequent blood cultures were negative, and the patient was discharged approximately 6 weeks after admission still maintaining an elevated nonprotein nitrogen.

He was seen 8 months later with no significant change in renal condition, and with a Grade IV harsh aortic systolic murmur and an aortic diastolic murmur.

CASE 3 (A. H. A43315). A 32-year-old man was admitted to the hospital with the chief complaint of spots on the legs. The spots had appeared 1 month prior to admission and had been associated with chills and fever. He had been studied by a physician, and the bleeding and clotting times were normal, one blood culture was negative. There had been an associated 24-pound weight loss.

The patient reported that the patient had had rheumatic fever as a child, but no murmur had ever been noted by his family physician. One year before admission the patient had been discharged from the hospital, and no murmur had been noted at that time, although specifically sought for in view of the past history of rheumatic fever. Eight months prior to the present illness, the patient had been hospitalized for hemorrhaphy, and at that time no murmur had been heard on examination of the heart.

Physical examination revealed a generalized alopecia, color to the skin and purpuric eruptions over the lower extremities. The spleen was palpable. The heart sound were described as being forceful. Two examiners noted no murmurs in the heart, whereas a third believed that there might be a very soft apical presystolic murmur.

The temperature was 100.4°F, the pulse 94, and the respirations 24. The blood pressure was 130/50.

Laboratory studies revealed a moderate leukocytosis and anemia. X-ray films revealed a mitral configuration of the heart. Blood cultures drawn on the first 4 days of the hospital stay were positive for hemolytic streptococcus.

Intramuscular administration of penicillin was begun at this time and continued for 4 weeks. A total dose of 21,000,000 units was given. The temperature fell to normal after the 1st day of this therapy and remained so throughout the remainder of the hospital course. During the hospital stay, a very loud, apical, systolic and presystolic murmur developed, with a diastolic murmur at the aortic area.

The patient was discharged after 6 weeks in the hospital, symptom free. He has been followed for a year and a half in the outpatient department, and at the present time he has Grade IV aortic and mitral systolic and diastolic murmurs.

SUMMARY

Three cases are reported in which permanent cardiac murmurs had their initial appearance during the course of bacterial endocarditis, successfully treated with penicillin. It is suggested that the absence of cardiac murmurs need not militate against the initial diagnosis of subacute bacterial endocarditis.

Correction. In the article entitled "Aureomycin in the Treatment of Primary Atypical Pneumonia," by Finland, Collins and Wells, which appeared in the February, 1955 issue of the *Journal*, the first sentence in the third paragraph on page 246 should be changed to read: "The patient with whom we are concerned in the present evaluation was acutely ill and febrile when aureomycin was started. In each the history and the physical, x-ray, and laboratory findings are all characteristic of primary atypical pneumonia."

MEDICAL PROGRESS

SYPHILIS*

G MARSHALL CRAWFORD, M D †

BROOKLINE, MASSACHUSETTS

THE preponderance of publications regarding syphilis continue to emphasize penicillin. A major impediment to penicillin therapy was its requirement of hospitalization. Subsequent development of repository types of penicillin products that require but one injection per twenty-four hours has practically eliminated the hospitalization factor. Continued improvement of these products and their wider application have proved successful. The time factor remains essentially the same whether rapidly utilized penicillins or slowly absorbed preparations are employed. Thus, a large majority of patients can be treated on an ambulatory basis, permitting more efficient utilization of clinic personnel, both professional and clerical. The ten-day treatment schedules that have been widely employed are resulting in a high percentage of patients completing their therapy in contrast to the frequent lapses and defections that accompanied traditional chemotherapy. The percentage of reactions is apparently no greater with repository penicillin products than with the rapidly absorbed types. Mentally incompetent patients are an obvious exception to ambulatory treatment and must, of course, be incarcerated. Cardiovascular syphilis and visceral lesions in which a Herxheimer reaction would be disastrous seem to be the only outstanding contraindications to treatment with penicillin in oil.

PUBLIC HEALTH

During the past ten years a nationwide campaign for the control of venereal disease has been in progress, headed by the United States Public Health Service. Remarkable strides have been made in all respects, and a gradual reduction of the incidence of all venereal diseases has been attained. The armed forces of the United States passed through World War II with the lowest venereal-disease rate of any nation in any major war. A rise in the civilian rates was feared in the postwar period, but control measures have been maintained with such efficiency that no appreciable increase has been recorded. Current methods of therapy are remarkably more efficient than ever before, but physicians cannot treat the disease until infected persons are at hand. Finding the infectious

patients and bringing their disease under control before it has been spread is the primary objective. Continued public interest and support is essential. There are three main points of primary importance: public education and information, mass blood testing examinations and contact tracing. Diligent pursuit of these case-finding activities will constitute the essence of future progress in the control of venereal disease.

Control Measures

Evidence that the aforementioned control measures are not being neglected in the postwar period is seen in publications from the Venereal Disease Division of the United States Public Health Service.^{1, 2} In a ten-year period the number of deaths due to all forms of syphilis has been reduced by a third, and the infant deaths by two thirds. This notable accomplishment is largely attributable to the nine basic principles of public-health control of syphilis. These include the development of a trained public-health staff, case-finding and case-holding technic, laws requiring premarital and prenatal serodiagnostic tests, the expansion of diagnostic services, the provision of public treatment facilities, the distribution of anti-syphilitic drugs by state health departments, emphasis on routine serodiagnostic tests, a program of scientific information directed to health officers and practicing physicians and a vast public-education campaign. One of the major accomplishments has been the transference of the word syphilis from the unmentionable category to everyday usage among the public. It is estimated that of all patients treated today for primary and secondary syphilis, two thirds voluntarily seek diagnosis as a result of public education among civilians and the information disseminated among the armed forces. Under the direction of the Public Health Service, extensive investigations into a wide variety of fundamental research problems have been under way for years. Greater emphasis will be placed on this work as one of the more important future potentialities. Thirty-five per cent of all cases of syphilis reported each year have been found by private physicians in the regular course of their daily practice. A still larger percentage is probably under treatment in the hands of the private physician, and authorities are in full cognizance of these facts. More assistance will be extended to the practicing

physician in the management of his cases and in case-finding activities

The Venereal Disease Division of the United States Public Health Service is implementing case-finding activities throughout the country by the preparation of fifteen-minute radio programs to be released through district offices for use by state and community health departments.³ These transcriptions will deliberately de-emphasize technical information, rather, they will stress when to suspect infection and where to go for treatment. The accent is on hope rather than fear. Various transcriptions are in preparation with special appeal to particular audiences such as sports fans, mystery-story fans, soap-opera fans and hillbilly-music followers. The scripts have been prepared by some of America's best radio writers, and the programs will feature well known performers. These transcriptions should have been released some time before the publication of this review.

The Chicago Health Department has made extensive use of telegrams in case-finding and case-holding at its intensive treatment center.⁴ Of 1541 contacts to whom telegrams were sent, 47.0 per cent reported to the health department within three days. A total of 225 patients, or 1 out of every 7 persons to whom telegrams were sent, were placed under treatment for primary or secondary syphilis. The telegram technic proved relatively inexpensive and was unobjectionable to the persons involved. It was not only effective but also time-saving.

Intensified campaigns to bring to light as much syphilis as possible have been carried out in many communities through the country. Almost uniform success is evident in numerous publications from all quarters. Particularly outstanding are the accomplishments in the State of Georgia.⁵ Here is an excellent illustration of what can be attained via the mass blood-testing technic, which was carried out in eight large communities between October, 1945, and August, 1947. Approximately 288,000 persons were tested, and a total of 9042 previously unknown cases of syphilis were discovered. During the special program, ten to forty-seven times as many new cases of syphilis were discovered as would ordinarily have been reported during an equal period. It was found that a large proportion of the population of a community will seek a blood test in response to an intensive publicity campaign, without the backing of a law. Intensive contact investigation conducted jointly with the mass blood testing led to the discovery of still more primary and secondary disease. These achievements set a remarkable example for most other states.

Mortality

Statisticians of the United States Public Health Service have prepared an analysis of the mortality

from syphilis for the years 1933-1945.⁶ The analysis begins with 1933 because that was the first year in which the entire United States was included in the vital-statistics registration area. Perhaps the most outstanding trend in this survey is the decrease in the total death rate from syphilis beginning with 1937 and continuing into 1946, the rate decreasing by approximately 25 per cent in that time. Syphilis remains a major cause of death, however, particularly in the Negro population—only eight conditions exceeded syphilis as a reported cause of death for Negroes in 1945. Improvement in therapy and treatment facilities has been an important factor. Intercurrent diseases that may cause death can also alter statistics. The difficulty of diagnosing syphilis as the cause of death may enter into the problem. The willingness of physicians to report syphilis as the cause of death when they have made the diagnosis may be influenced toward concealment because of social taboos or insurance policies that exclude syphilis as a mortality risk. All these factors are more or less constant, however, and should serve only to reduce the over-all quantity of reported cases. It is considered by the Public Health Service that the reporting by physicians has actually improved. The trend of infant deaths from syphilis per 1000 live births has been in the same direction as the general mortality trend, although the rate of decrease has been greater in the infant group, dropping from 0.79 to 0.25 during the thirteen-year period of analysis.

Statistical Trend

In 1948 there were indications in various publications that the syphilis rate in the United States had increased alarmingly since the end of the war. Statistics from the United States Public Health Service contradict these claims.⁷ Statements were presumably based on the number of cases of early syphilis reported among civilians rather than on rates calculated for the whole population of the United States. The tables do indicate a moderate increase of early syphilis among civilians in 1946 and 1947, but this was undoubtedly due to the return to civilian life of millions of young adult men in the age group in which new syphilis infections frequently occur. At the same time there has been a steady decrease in the rates of congenital and late syphilis, and the total syphilis reported has shown a continuous decline from 1933. When the total of civilian and armed forces is considered, the early infections actually showed a decrease in 1947 as compared to the year before. A survey of the reasons for reporting to venereal-disease clinics indicates that 64.2 per cent of patients came of their own initiative.⁸ This was a widely scattered study covering several districts in each of seventeen states. Such a large percentage of voluntary clinic attendance portends the value of public education regarding venereal disease. The same analysis

obviously the most potent preparation, and penicillin K the least potent, whereas F and X hold intermediate positions between these extremes. Crude sodium penicillin is probably more effective than F, X or K. Bacitracin is also relatively inefficient.¹⁶

Methods of Administration

The optimum time-dose relation in the administration of penicillin for the treatment of syphilis is yet to be established. At least three variables may modify therapeutic efficiency: the number of injections, their frequency and the total amount of penicillin administered. It has been shown in experimental rabbit syphilis that the greater the number of injections, the less the total amount of penicillin required for cure.¹⁹ Lengthening the duration of treatment has a similar effect on the curative dose. When injections were given so frequently as to produce cumulative effects on the penicillin blood level, therapeutic efficacy was paradoxically reduced. Although the therapeutic action of penicillin clearly involves both the tissue concentration and the time over which it acts, the latter time factor is by far the most important. Low concentrations acting over a long period are more effective than high concentrations for a short period. Thus the interval between injections is not so important, provided they are not given too often. The use of any procedure that delays the absorption and excretion of penicillin should have the same effect as increasing the frequency and number of injections.

In a comparison of subcutaneous versus intramuscular administration of penicillin, there were no significant differences in the plasma penicillin levels.²⁰ Three purified preparations, the amorphous, and crystalline sodium penicillin and crystalline potassium penicillin, gave essentially the same results. It has been demonstrated that penicillin is readily absorbed through the vaginal mucosa and appears in the blood in high therapeutic levels.²¹ Ten patients were used, and although there were wide individual variations, probably owing to loss of penicillin from the introitus, therapeutic levels were maintained up to three hours in all cases. Rabbit syphilis can be controlled by oral administration of penicillin, but the curative dose is excessive.²² This approach is not advisable in the human disease.

There is further confirmatory evidence of the value of penicillin oil in the treatment of rabbit syphilis.^{23, 24}

Prolonged Penicillin Action

Earlier products with penicillin in oil and beeswax had the disadvantage of being solid at room temperature and therefore difficult to administer. Liquid preparations of penicillin in oils that are fluid at room temperature and comparable in com-

position with the original products are now available commercially. The duration of the penicillin blood levels following the intramuscular injection of these "liquid" preparations has been studied and found satisfactory.²⁵ A procaine salt of penicillin G suspended in sesame oil has been employed at the Mayo Clinic and elsewhere with approval.²⁶⁻²⁸ The maximum serum penicillin concentrations obtained with procaine penicillin G in oil were lower than those after a similar dose of the oil and beeswax product but showed considerably more uniformity throughout the twenty-four hours following injection. A still further improvement in these repository types of penicillin products is claimed with the introduction of the principle of suspending penicillin salts in peanut oil, jelled with 2 per cent aluminum monostearate.²⁹ Several salts of penicillin were tested in this vehicle, and the absorption was delayed longer than when the same salts were suspended in peanut oil alone or in peanut oil and wax. Aside from the occasional allergic reaction to penicillin, there was no case of undue irritation or untoward effects although the series of patients treated was small.

A possible further fruitful avenue is the study of insoluble metallic and organic salts of penicillin.^{30, 31} Insoluble salts with heavy metals have not been extensively used because such metallic ions inactivate penicillin. It was found however that insoluble metallic and organic salts of penicillin were apparently reactivated *in vivo* and produced quite respectable penicillin blood levels in rabbits as long as twenty hours later. This work bears further study.

Continued investigation of the effect of caronamide for its value in prolonging the effective therapeutic levels of penicillin has been encouraging. In experimental pneumococcal and typhoid infections in mice it is apparent that a therapeutic effect may be obtained with much smaller doses of penicillin when caronamide is administered concomitantly, and that higher and more prolonged penicillin levels are obtainable with caronamide than with similar doses of the antibiotic administered alone.³² It has been demonstrated that caronamide has no intrinsic bacteriostatic activity and it does not increase the *in vitro* bacteriostatic effect of penicillin so that the intensified *in vivo* effect of penicillin in the presence of caronamide should be due to enhanced and prolonged penicillin plasma levels. This suggests that infections caused by organisms relatively resistant to penicillin might be within the limits of practical penicillin therapy if caronamide were used. The effect of the latter drug has been found to be greater in older persons.³³ The only toxic effects noted have been nausea and mild diarrhea in a few cases. Caronamide can be used orally in conjunction with the oral administration of penicillin but is much more effective when the latter is given by intramuscular injection. Its

pointed out that almost 25 per cent of the patients with previously untreated primary or secondary syphilis came to the clinic as a result of contact investigation. Such an appreciable figure illustrates what can be accomplished by efficient case-finding and contact-tracing measures. The remaining small percentage came for other reasons such as prenatal or premarital blood testing, health-card applications and police or court orders, and because of blood examination for selective service or on separation from the armed forces.

EXPERIMENTAL STUDIES

It has been known for some time that processed blood stored in banks does not transmit syphilis regardless of infection in donors. New confirmation of this fact is in evidence from animal experimentation.⁹ Rabbits inoculated with stored dried material failed to develop evidence of syphilitic infection during three successive subtransfers observed for as long as thirteen months. It was obvious that *Treponema pallidum* suspended in saline-blood serum becomes avirulent and is apparently killed during the freezing and drying procedures. The danger of transfusion syphilis obviously seems to be eliminated with the use of processed human plasma or blood.

Immunity

It is accepted that at least some degree of true immunity develops during the course of syphilitic infection. Numerous efforts to produce this immunity by artificial means have been uniformly unsuccessful. A new attempt by the repeated subcutaneous injection of lyophilized spirochetes alone and with adjuvants failed to protect rabbits against minimal infectious inoculums of *T. pallidum*.¹⁰ It was observed that the injection of these antigens did produce positive serologic tests for syphilis in the same animals, this response should at least indicate a reaction in the host and provide some encouragement for investigators in that field. The relative cross immunity among three varieties of treponemes has also been investigated in rabbits.¹¹ Syphilis, yaws and venereal spirochetosis of rabbits were each found to generate some degree of immunity against treponemes causing the other infections concerned, as compared to control groups. The inoculations used probably contained many times the minimal infective dose of the various organisms, which subjected the acquired resistance of the animals to an unusually severe test. The definitely greater resistance to *T. pallidum* certainly indicates further study of the potentialities of other treponemes as immunizing agents. Methods of counting spirochetes have made possible the determination of the minimal infectious inoculant, which has proved to be one spirochete.¹² One or two spirochetes were regularly infectious to rabbits. There was no appreciable effect on incubation

period until as many as 10,000 organisms were injected. An inoculum of 200,000 organisms brought about another distinct decrease in incubation period. A rigid control of the size of the inoculant is obviously necessary for experimental studies on chemoprophylaxis, abortion or treatment of syphilitic infection. This same work with skin inoculation experiments enabled an estimation of the average rate of multiplication of the spirochetes in vivo to be thirty hours for each division of one spirochete into two spirochetes. Further study, with the application of this information to rabbit syphilis, revealed that progressively larger doses of penicillin were necessary to protect the animals as the size of the inoculum was increased.¹³ In another phase of the work, when a fixed intratesticular inoculation was used, the amount of penicillin necessary to prevent infection remained at a constant level for four days. By the end of the second week more than seven times this dosage was needed to prevent infection, and by the end of the sixth week, after a chancre had appeared, more than thirty times the amount was required. This leads to speculation regarding the possibility of aborting syphilis in man by small doses of penicillin administered during the incubation period. If rabbit syphilis and human syphilis are comparable, and assuming that penicillin behaves similarly in both, comparatively small amounts of penicillin might be hopeful abortive therapy in some early infection if given as soon as four days after exposure.

Further evidence that immune factors do occur in rabbit syphilis is now available.¹⁴ A sizable group of animals was inoculated with syphilis, observed for eight months, given a known curative dose of penicillin and, ten days later, reinoculated. Only 53 per cent were found to be reinfected, and theirs was a symptomless invasion, the syphilis having been proved by transfer of lymph nodes to normal animals for proof of the infection. When the same procedures had been carried out in early syphilis of rabbits, 73 per cent presented a symptomless reinfection. It is obvious therefore that the immune factors occurring in early latent syphilis are more forceful than those observed in early infectious syphilis. The potency of the protective reaction varied with the duration of the disease.

Species of Penicillin

A co-operative investigation of the efficacy of several species of penicillin in the treatment of experimental syphilis corroborates earlier knowledge that penicillin G is by far the most effective specimen.¹⁵ Penicillin F required about six times as large a dose as penicillin G to achieve the same effect. Penicillin K was distinctly inefficient, and the data on penicillin X were so discrepant as to be insufficient for comparison. Further independent studies are corroborative.¹⁶⁻¹⁸ Penicillin G is

SEROLOGIC PROBLEMS

Cardiolipin

In the last few years cardiolipin has been employed as a new phospholipid content of antigens for serologic tests for syphilis. It was hoped that this new substance would be the answer to simplification or clarification of the serology of syphilis. So far cardiolipin has not fulfilled either role. There have been improvements, but even more technics seem to have appeared and simplification is far from achieved. The clinician who interprets the results of laboratory procedures for his patient still cannot shift any responsibility from his own shoulders to that of the laboratory technics or the personnel performing them.

The Venereal Disease Research Laboratory slide flocculation test for syphilis was one of the first to employ the cardiolipin antigen and has been studied most extensively.^{44, 45} More than 8000 serums from syphilitic donors taken before, during and after treatment have been examined by this technic. An analysis of results with comparative tests indicates that the slide test functions at a satisfactory level of sensitivity, produces a relatively low proportion of weakly positive reactions and yields satisfactory specificity on specimens from nonsyphilitic persons. In the laboratories of the New York City Department of Health this test was compared with the Mazzini and Kahn flocculation tests and the Kolmer complement-fixation test in 57,372 routine specimens.⁴⁶ The sensitivity of the four tests, in order of reactivity, was the Mazzini slide test, the Venereal Disease Research Laboratory slide test, the Kolmer complement-fixation test and the standard Kahn test. The reliability of the Mazzini and the Venereal Disease Research Laboratory procedures as screening tests was attested by their agreement in the negative reaction in all but 0.8 per cent.

Hinton⁴⁷ has tested about 1000 carefully selected specimens by his technic with an antigen prepared from cardiolipin and lecithin. Results appear to be just as specific, but considerably more sensitive than those obtained with the Hinton test when the indicator was prepared from an extract of beef heart. Kahn has studied the effect of various lipids on his serologic tests and reports that lecithin can be used to correct oversensitive antigens since it reduces their reactivity.⁴⁸ On the other hand cephalin was found to increase the sensitivity of undersensitive antigens to bring them up to the requirement of the standard Kahn antigen.

A comparison of the cardiolipin and Kline antigens appears in a report of clinic and serologic evaluation of 27,103 consecutive slide tests for syphilis with optimum cardiolipin-lecithin antigen and Kline antigen.⁴⁹ The cardiolipin slide test gave results of decidedly greater specificity and much greater sensitivity than diagnostic Kline antigen

emulsion and was also distinctly more specific in nonsyphilitic serums than the Kline exclusion antigen emulsion. Kline⁵⁰ himself advocates the use of a single standard test employing the cardiolipin antigen. He believes that the flocculation reaction is better suited for use in the standard test for syphilis than in the complement-fixation reaction, which requires more ingredients and more time. He further believes that the slide technic offers more advantages for a standard test than the tube flocculation technic. The application of cardiolipin antigen to the Kline procedure is reported from another laboratory, with highly satisfactory results in a large series of cases.⁵¹ The test showed a significantly higher sensitivity than either the standard Kahn or the Kolmer test, and the specificity was essentially the same as that shown by the Kahn reaction. In the special instance of malaria the specificity of the cardiolipin test was outstanding.

The cardiolipin antigen has also been successfully adapted for use in the Kolmer complement-fixation test for syphilis.⁵² Cardiolipin antigen was found slightly more sensitive than the standard Kolmer technic in testing known syphilitic serums. Specificity was essentially the same with the two procedures in testing known nonsyphilitic persons. Specimens from patients with active yaws showed the same relative reactivity in the two tests.

Quantitative Tests

Quantitative determinations can be made by means of both flocculation and complement-fixation technics through a series of dilutions. Their employment is indicated in conjunction with intensive antisyphilitic treatment for appraisal of the various methods during treatment and in follow-up study of the early syphilis so treated. Further value lies in detecting serologic relapse before clinical evidence appears, in darkfield-negative primary syphilis (in which a low but increasing titer may be of great significance) and with suspected congenital syphilis in the newborn. Quantitative tests also have certain value in attempts to decipher a possible false-positive reaction, especially since none of the verification tests so far developed have been completely satisfactory.

A rapid slide flocculation test for the titration of antibodies in syphilitic serum has been described.⁵³ The data presented indicate that this test may be satisfactorily substituted for the conventional tube dilution procedure using either the cardiolipin or Mazzini antigens. An application of the Kahn "optimal zone reaction" has been described for use in seronegative cases of neurosyphilis.⁵⁴ This technic is more specialized than the usual quantitative reactions but may be worth while in some of the puzzling infections of the central nervous system in which other serologic reactions are consistently negative. Most reviews of the various tests and

effect is less constant when it is used in conjunction with the injection of penicillin in oil. Sodium benzoate has been found as effective as caronamide in increasing plasma penicillin concentrations.³⁴ The ingestion of both sodium benzoate and caronamide by subjects receiving penicillin by mouth resulted in a greater enhancement of plasma penicillin concentration than that achieved by either of these agents alone. Although caronamide has not yet been widely used, it is thought to be free of renal, bone-marrow or hepatic effects, and has not yet been observed to produce dermatitis or drug fever.³⁵ Caronamide is administered by mouth, usually in doses of 2.0 gm every three or four hours, concomitantly with penicillin. Its effect as a renal "retardant" begins to wear off after two hours.

In a dissertation on the significance of penicillin blood levels, Eagle³⁶ points out that concentration of penicillin in the blood has significance only in that it "provides a rough measure of the concentration at the foci of infection in the tissues." Thus, the therapeutic effect of a given dosage of penicillin depends on the total length of time the concentration of penicillin in the blood is at maximal bactericidal levels. The danger is greater with organisms that recover rapidly from penicillin action or multiply at a fast rate than with organisms that multiply only slowly, such as *T. pallidum*. It is obvious that the plasma level of penicillin should not be allowed to drop below the concentration that, in vivo, is sufficient to kill the organism in question faster than the organism can multiply. Another communication presents tables and graphs that enable the physician to determine the frequency at which a given dose should be injected and the dosage of penicillin that should be used at stated intervals to maintain given concentrations of penicillin in the plasma.³⁷

Other Therapy

Bismuth has been widely employed as an adjunct in the penicillin treatment of syphilis, but there has been little direct experimental evidence supporting such use. It is known that mapharsen and penicillin are synergistic in experimental syphilis, and by analogy it has been assumed that bismuth might similarly aid the spirocheticidal action of penicillin. A study of experimental rabbit syphilis has been confirmatory.³⁸ Bismuth and penicillin were shown to be as synergistic as mapharsen and penicillin, and bismuth should apparently be as effective as mapharsen in this combination. Maximum synergism was obtained when bismuth and penicillin acted simultaneously through the use of a water-soluble bismuth preparation. This is because of the delayed absorption of bismuth salicylate, which, however, also reduced the curative dose of penicillin whether given during or after the penicillin treatment. Bismuth did not affect

the penicillin blood level. Since bismuth is so relatively innocuous as compared to mapharsen, it should obviously replace the latter for combined therapy with penicillin.

A bismuth salt suitable for oral administration has been shown to produce therapeutic levels and is on the whole well tolerated.³⁹ Relatively few patients with early syphilis have been treated with this agent, responses were typical of systemic bismuth therapy. Bismuth by mouth is certainly not to be recommended for the treatment of syphilis in any stage unless more effective measures are contraindicated. Nevertheless, it might prove with further study to be useful as an adjuvant therapy in conjunction with penicillin.

The value of fever therapy alone or in conjunction with other methods has long been appreciated in the treatment of late syphilis, especially neurosyphilis. Recent studies have been undertaken to determine the possible application of this modality to early syphilis. It has proved useful, though more hazardous than other approaches, and reports are still appearing to that effect.⁴⁰ Penicillin therapy has almost entirely superseded such drastic forms of treatment, but they may be kept in mind for infrequent resistant cases.

A post-mortem study of the aortas of 45 patients with syphilitic aortitis bears out the long-established tenet that even traditional chemotherapy exerts a profound influence on the inflammatory process in the aorta.⁴¹ Nineteen of these patients had received the so-called minimal standard therapy of approximately 20 arsenical and 20 bismuth injections, and only 3 of them exhibited active inflammation in the aortic walls. Progressively greater activity was observed as the amount of treatment decreased. There was apparently no correlation between the duration of infection and the activity of the aortitis. The isolation of virulent *T. pallidum* from the aorta thirty-two hours after death is most interesting, since the demonstration of viable treponemes is generally considered difficult in late lesions.⁴² Aortic tissue was inoculated into a rabbit thirty-two hours after the death of the patient in this case. Viable organisms were also isolated from juxta-articular nodules. The patient had had syphilis for twenty-five years and had received no therapy. This event is obviously of practical importance to pathologists from the standpoint of possible accidental infection during post-mortem examinations. Motile spirochetes have been found in human autopsy material refrigerated for as long as forty-eight hours.⁴³ In fresh material from infectious lesions, viable treponemes can be maintained in an incubator of 37°C for as long as fourteen days. The enormous numbers of *T. pallidum* that may be found in macerated fetuses suggest the possibility that this organism can multiply in dead tissue under anaerobic conditions.

all publications show a failure rate of 10 per cent or higher, which is too large for complacency.

Numerous words of caution have been uttered regarding the danger of masking early syphilis with the penicillin treatment of gonorrhea. This has been excellent advice. There is one report available of 19 cases of early syphilis observed to develop after 150,000 units of penicillin for gonorrhea.⁶³ The appearance of syphilis was not delayed longer than three months in any case. These observations should actually serve as another word of warning, since the amount commonly given for gonorrhea is 300,000 units of penicillin. One could reasonably expect that this dose would delay the appearance of early syphilis for a decidedly longer time. A follow-up period of not less than six months seems only reasonable for penicillin-treated gonorrhea patients.

Syphilitic Chancres

In a survey of 680 male patients with early syphilis one observer found the primary lesion on the glans penis in approximately half the cases.⁶⁴ Twenty-five per cent of the chancres were on the prepuce, 15 per cent were on the penile shaft, and 10 per cent were paragenital or extragenital. An interesting observation in that series was the fact that chancres on the shaft of the penis were seldom indurated. There were multiple chancres in only 12 per cent of the patients observed. In another series of similar size, the surprisingly higher figure of approximately 40 per cent multiple chancres was found.⁶⁵ The incidence of multiple lesions was consistent in both sexes. If multiple chancres actually occur as often as this figure indicates, older teachings must be revised. These reports should stimulate the physician to be more on the alert for multiple chancres that might otherwise mislead him to the extent of mistaken diagnosis or perhaps undue delay in establishing a correct appraisal of primary syphilis.

Extragenital chancres are a still more likely possible cause of incorrect or unduly delayed diagnosis. A low index of suspicion of the primary lesion of syphilis is bound to interfere with its recognition when the location is extragenital. Early diagnosis is of greatest value in primary syphilis, not only from the standpoint of the patient, whose chance for a true biologic cure diminishes with time but also from the viewpoint of transmission of the disease to others. A study of 219 patients with extragenital chancres has been published from the Johns Hopkins Hospital.⁶⁶ A significant preponderance of extragenital lesions occurred in the female patients and in the white race. In the majority immediate sexual contact with infectious lesions of syphilis seemed the most likely explanation. Except in children, by far the largest number of extragenital chancres occurred in or adjacent to the buccal cavity. Multiple extragenital initial lesions occurred in only 9.4 per cent of the patients.

A surprising frequency and variety of erroneous diagnoses were found in the records. Any indolent indurated lesion anywhere on the body, especially if accompanied by unilateral adenopathy, should warrant the suspicion of syphilis. The diagnosis rests on the use of the darkfield microscope and serologic tests for syphilis.

Penicillin Therapy

Treatment schedules in use during the early history of penicillin often employed dosage plans that proved to be too small. An illustration is a series of over 400 cases of early syphilis treated with 1,200,000 units over a period of three and three-fourths days.⁶⁷ Twenty per cent of this group were found to be treatment failures at the end of fifteen months' observation. Rapid penicillin treatment, employing massive doses intravenously, has also proved unsatisfactory.⁶⁸ A group of 129 patients received 10,000,000 units of penicillin intravenously in a twenty-four-hour period, but the treatment failed in approximately half the group. Another series of 275 patients with early syphilis were given from 10,000,000 to 25,000,000 units by the continuous intravenous drip method over a period of twenty-four hours.⁶⁹ Even with the maximum dosage 35.2 per cent were failures, indicating an obviously ineffective treatment schedule. Reactions to therapy were frequent but generally mild, and all patients having reactions recovered rapidly. The obvious inadequacy of these attempts at rapid massive penicillin therapy is a perfect example of the importance of the time factor in treatment. Almost all studies of penicillin treatment have indicated that shortening the elapsed time of therapy cannot be counterbalanced by increasing dosage.

An analysis of 22 different treatment schedules employing penicillin for previously untreated secondary syphilis, utilizing at least 50 patients for each, has been published by the United States Public Health Service.⁷⁰ In some plans penicillin was used alone, and in others various adjuvants were employed. The optimum therapy schedule appeared to be 3,400,000 units of penicillin in aqueous solution given in injections of 40,000 units each at two-hour intervals (seven days). Results were tabulated at twelve to fifteen months after therapy. Treatment and follow-up data were furnished by fifty state and locally sponsored rapid-treatment centers. Poorest results were obtained with schedules in which the total amount of penicillin was given in thirty hours or less regardless of dosage or adjuvant therapy. A subsequent report from the same source summarizes the principal facts of clinical importance in all phases of syphilis.⁷¹ It is pointed out that up to the end of 1947, at least 500,000 patients with syphilis in various stages had been treated with this antibiotic, the agent most employed in syphilotherapy in the United

their respective significance or special points of application point out the complexity of the problem.⁵⁵ Harris⁵⁶ has described a simplified reporting method that may be applied to all flocculation and complement-fixation tests for syphilis that employ serum and spinal-fluid dilutions. Quantitative reporting is not similar for the many different tests for syphilis, even in cases in which a common term such as "units" is used. The units of one testing procedure may have no constant relation to the units of another. The differences in reported titers are attributable to the dissimilar methods of calculation and interpretation applied to observed findings. It is suggested that quantitative serologic reactions be reported in terms of the greatest dilution in which the tested specimen produces a positive reaction. By this means, reactions of identical intensity would receive the same report in terms of dilutions, even when different testing methods are employed. This method of reporting can be incorporated into a testing routine without modification of existing test mechanics, and the reactivity levels would not be affected. Such simplified reporting would remove much of the unwarranted burden of confusion in cross interpretation that is placed upon the clinician.

False-Positive Reactions

No outstanding advance has as yet been reported toward the solution of the dilemma of false-positive serologic tests for syphilis. Kolmer⁵⁷ says that no test can be sufficiently sensitive for the detection of all cases of syphilis. He points out that any method now in use can be made more sensitive by technical modifications but only at the expense of increased falsely positive reactions. It is obviously far better to miss the serum diagnosis of an occasional case of chronic syphilis than to incur the risk of false-positive reactions in nonsyphilitic persons. Accurate clinical judgment should not be overruled by negative reactions, but at the same time positive serologic reports cannot be ignored simply because they seem to be the only evidence of disease. False-positive reactions may be suspected when they are consistently weak or doubtful with occasional strong positive reactions. Discrepancies in serologic reports from different laboratories should be suspected. A third clue is consistently negative complement-fixation reactions in the face of positive flocculation tests. In any of these circumstances a diagnosis should probably be withheld, with repetition of testing procedures at regular intervals over a period that may extend as long as six months.

In recent years smallpox vaccination has been repeatedly maligned as a cause of false-positive reactions in serologic tests for syphilis. The limited variola epidemic in New York City in 1947 gave rise to a city-wide vaccination program and provided an excellent opportunity for the study

of possible false-positive reactions for syphilis. Over six million persons were vaccinated, but no increase was noted in the percentage of serologic reactors during the period following the mass vaccination program.⁵⁸ All routine blood specimens forwarded to the New York Bureau of Laboratories are screened by the Mazzini slide test, and positive or doubtful serums are confirmed by the standard Kahn and Kolmer tests. Vaccinations against smallpox may occasionally produce a false-positive serologic test for syphilis, but it need seldom be confused with true syphilitic reactions if tests are employed during a period of observation extending over several weeks. Perhaps undue emphasis has been placed on this possible cause of serologic confusion. Although not primarily under suspicion, penicillin therapy has been ruled out experimentally as a source of false-positive reactions for syphilis.⁵⁹

In one survey of the enigma of serodiagnosis in syphilis, it is pointed out that high specificity rather than high sensitivity should be the primary aim of the serologic test.⁶⁰ Three main reasons for the occurrence of false-positive tests are emphasized: technical errors, presence of reagent in the blood of normal persons and affliction with a nonsyphilitic disease that produces a positive reaction. It is pointed out that the various stages of syphilis react differently to the serologic tests and that they are least dependable in untreated latent syphilis, in which results are variable. It should be stressed that even the most competent syphilologist with extensive laboratory facilities at his disposal will frequently be confronted with serodiagnostic problems that are incapable of solution without prolonged periods of repeated testing and that the ultimate decision often cannot be reached on the basis of laboratory findings alone. A thorough history and careful complete physical examination are required before the combination of clinical judgment and serologic reports can be correctly analyzed.

Complement-fixation tests are occasionally impeded by anticomplementary serum. A procedure has been outlined that seems to permit the satisfactory performance of a Wassermann test on such anticomplementary serums.⁶¹ A colored slide flocculation test for the diagnosis of syphilis has been described.⁶²

EARLY SYPHILIS

Penicillin has been used more extensively in the therapy of early syphilis than in any other phase of the disease. Although this form of treatment has been eminently successful, the multiplicity of therapy programs that are being tried and the variation in schedules that have been recommended are proof that selection of the ideal penicillin regimen for early syphilis is still far off. Most plans of treatment require 2,500,000 units or more of penicillin in not less than seven or eight days, many advocate far higher dosage and longer time schedules. Almost

States today It was stated that penicillin in oil and wax constituted the only practical method in the treatment of syphilis and provided proved effective blood levels of at least three to five times the duration afforded by aqueous penicillin in comparable amounts The recommended dosage for early syphilis in that report consisted of 4,800,000 units, with intramuscular doses every two or three hours for a period of seven and a half days The schedule advised for ambulatory treatment with crystalline penicillin in oil and wax consisted of the intramuscular administration of 6,000,000 units in ten injections over a period of ten days Adjuvant therapy with arsenic, bismuth or fever was advised as a combined therapeutic attack in patients who failed on an original course of penicillin alone A chart entitled "Examples of Acceptable Penicillin Schedules" advocated by the Venereal Disease Division of the United States Public Health Service is readily obtainable⁷² This provides at a glance the optimum treatment schedules recommended as a result of the aforementioned studies Reprints of the report on which it is based are available from the same source

The highest percentage of satisfactory results encountered in the treatment of early syphilis was reported from Bellevue Hospital⁷³ The series comprised only 59 patients, and they were treated with 26,666 units of penicillin G every two hours to a total of 2,400,000 units, satisfactory results were recorded in 58 cases, with a follow-up period of six months or more (98.2 per cent) With twice that dosage the satisfactory percentage was 97.3, and the author believed that most of the so-called failures were probably reinfections The data presented favored injections of penicillin G every two hours for ninety doses rather than every three hours for sixty doses, and suggested that a total of 2,400,000 units of penicillin was satisfactory in early syphilis A later report indicated no change in opinion⁷⁴

Confirmation of the superiority of a two-hour schedule of injections versus a three-hour interval is available from other sources⁷⁵ A three-hour schedule is advocated by the Mayo Clinic⁷⁶ Still other routines have been attempted, with varying degrees of success⁷⁷

Penicillin in oil As stated above, the United States Public Health Service survey strongly advised penicillin in oil and wax as the really practical method for the treatment of syphilis⁷¹ This method does not require hospitalization and is therefore suitable for office and clinic administration Ten daily injections totaling 6,000,000 units was the advocated dosage In a group of 802 patients receiving only 4,800,000 units over a period of eight days, 85.1 per cent satisfactory results were observed among 529 who were followed for nine months or more⁷⁸ The author believed that half the failures in this group were probably due to re-

infections Even without the estimated reinfections, a satisfactory average of 85.1 per cent is an improvement over the old standard chemotherapy results, since the over-all average for early syphilis by traditional therapy was approximately 75 per cent satisfactory results⁷⁶ There are two reports on a small group of patients who received only 300,000 units of penicillin in oil and beeswax daily for ten days, or a total of 3,000,000^{78 79} Of an original series of 238 patients, 136 were followed from three to eighteen months, with a failure rate of only 14 per cent This may have been somewhat optimistic since relapse is often not observed until after the first three months has passed Follow-up periods of not less than six months and preferably of a year or more are highly desirable before such a survey is presented

(To be concluded)

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

Weekly Clinicopathological Exercises

FOUNDED BY RICHARD C CABOT

TRACY B MALLORY, M D, *Editor*

BENJAMIN CASTLEMAN, M D, *Associate Editor*

EDITH E PARRIS, *Assistant Editor*

CASE 35101

PRESENTATION OF CASE

A twenty-two-year-old USO worker was admitted to the hospital complaining of frequent bloody stools, diarrhea, abdominal distention and increasing weakness.

The patient was in good health until four years before admission when occasional attacks of crampy lower abdominal pain and loose stools appeared, occurring two or three times each day. These continued without marked remissions or exacerbations for about a year. At that time, three years before admission, a fever appeared, the frequency of the bowel movements increased and the stools contained a little blood. She was hospitalized for a month, and a diagnosis of amebic dysentery was made, although the organism was not found. Diodoquin and emetine were employed with alleged improvement. After discharge she was somewhat improved but was extremely weak. She remained at home for two months and then was able to work. Two years before admission the attacks of diarrhea and abdominal, cramp-like pain recurred, and she was unable to continue working. Three months before admission, during a severe attack, she developed abdominal distention and ankle edema and she was admitted to another hospital. The edema and distention subsided, and she returned home on a low-roughage, low-fat and kapectate regime. Two weeks before admission the pain became more severe, and the stools were increasingly large, loose and bloody. The weakness and prostration became so great that she could not sit up in bed, and this precipitated her admission to this hospital.

For some time she had had frequent epistaxes and bleeding gums but no hematuria, hemoptyses, ecchymoses or jaundice. She had vague joint symptoms in the past. No menses had occurred for two years. At the age of fifteen a thyroidectomy had been performed for toxic goiter.

Physical examination showed an apprehensive, drowsy and somewhat incoherent patient in no acute distress. The skin was warm, dry and pale, the tongue was dry, slightly smooth and red. The

eyes were slightly prominent. Small, firm, non-tender, movable axillary nodes were palpable. The breasts were underdeveloped for her age, the pubic-hair pattern was normal. Both leaves of the diaphragm were high. The abdomen was very distended and tympanitic but flat in the flanks. No tenderness or spasm was present. The liver and spleen were not felt. Peristalsis was high-pitched but not tinkling.

The temperature was 99.2°F, the pulse 140, and the respirations 20. The blood pressure was 110 systolic, 40 diastolic.

The hemoglobin was 6.6 gm. The white-cell count was 16,200, with 80 per cent neutrophils, 12 per cent lymphocytes, 4 per cent monocytes, 3 per cent eosinophils and 1 per cent lymphoblasts. The red blood cells showed marked achromia and considerable variation in size. The urine showed a specific gravity of 1.012, with a ++ test for albumin and a ++ test for bile. Forty red blood cells and 10 white blood cells per high-power field were seen in the sediment.

The fasting blood sugar was 100 mg, the serum albumin 3.59 gm, and the globulin 1.87 gm per 100 cc. A prothrombin time was 28 seconds (control, 14 seconds). The chloride was 99, the sodium 136.8, and the potassium 5.9 milliequiv per liter. The nonprotein nitrogen was 44 mg per 100 cc, the van den Bergh reaction was 3.9 mg per 100 cc direct and 6.6 mg indirect. A blood Hinton test was negative. The stools were liquid and reddish dark brown, and no ova or parasites were seen. On proctoscopy the bowel wall was red and edematous. When wiped it was finely granular and bleeding. No large ulcerations were seen. An x-ray film of the abdomen taken with a portable machine demonstrated considerable distention of the stomach. Gas was also visualized in the ascending, transverse and descending colon.

The patient did poorly. Therapy included intravenous fluids, blood transfusions, chloromycetin, penicillin and sulfadiazine. Turpentine stipes were applied to the abdomen. Chloral hydrate, paraldehyde and demerol were employed for sedation. Abdominal distention increased, and peristalsis stopped. On the third hospital day icterus was noted, and the breath had a "mousy" odor. Multiple spider angiomas were seen on the anterior chest and neck. On the sixth hospital day the blood showed a serum albumin of 2.06 gm and globulin of 3.74 gm per 100 cc, sodium of 120.1, chloride of 90 and carbon dioxide of 18.4 milliequiv per liter. The van den Bergh reaction was 6.8 mg per 100 cc direct and 9.8 mg per 100 cc indirect, the prothrombin time was 26 seconds (control, 14 seconds), and a cephalin flocculation test was ++++ in twenty-four hours. In the evening the patient had a tonic convulsion, with the jaws clenched and the tongue between the teeth. This was relieved almost immediately by 10 cc of cal-

cium levulinate intravenously. On the following day the serum calcium was 6.5 mg per 100 cc, and the carbon dioxide 17.1, the sodium 125.8 and the chloride 92 milliequiv per liter.

She remained afebrile, but her condition rapidly deteriorated. Kussmaul breathing appeared, and the chest became full of rhonchi. The jaws were locked, an anesthesia airway was maintained. On the eighth hospital day she died.

DIFFERENTIAL DIAGNOSIS

DR MARIAN ROPES. This patient surely had involvement of at least three major systems: the gastrointestinal tract, the liver and the kidney. I will attempt to consider them separately and see whether or not they can be related and, if so, how.

The initial involvement was the gastrointestinal tract. I think that the entire history up to the time of admission is consistent with idiopathic ulcerative colitis. It is impossible to rule out other forms of colitis entirely on the record or by information that was available. Amebic dysentery cannot be ruled out entirely. There are a good many points against it, and the so-called response or partial response to treatment is not very impressive. It could have explained the apparent remission with a subsequent exacerbation after the remission. However, the strongest point against amebic dysentery is the proctoscopic examination showing a finely granular bleeding membrane and no ulcerations. The fact that ova or parasites were not identified does not rule out any of the parasitic diseases. Tuberculosis would have to be considered but can readily be discarded. The course would be extremely unusual with the relatively long period of remission. So I shall assume that the first part of the illness was due to idiopathic ulcerative colitis.

At the time of admission to the hospital the patient was perhaps somewhat sicker than one would expect from the degree of colitis that she had, and in the absence of fever at that time and with no more evidence of change in the sigmoid than was found. The only other things in the history before admission that might be mentioned are the vague joint symptoms in the past, which are consistent with ulcerative colitis. I believe, although I am not sure, that Dr Jones finds joint symptoms in 10 per cent of cases of ulcerative colitis. The joint symptoms vary greatly from arthralgia, which I judge she had, to true infectious arthritis or to a picture indistinguishable from rheumatoid arthritis.

Examination at the time of admission is consistent with ulcerative colitis. I think she probably also had arthritis, although we are not given enough information to be sure.

The laboratory findings are in general also consistent. The hemoglobin of 6.6 gm can be explained by the blood loss, which I judge had been rather great. The prolongation of prothrombin time could have been entirely secondary to the diarrhea and

associated with loss of vitamin K. On the other hand, it does suggest involvement of the liver, and in the presence of that and the elevated van den Bergh reaction liver involvement is strongly indicated. Similarly, the urinary findings and elevated nonprotein nitrogen surely suggest some renal involvement. For the moment I will not discuss that further but will go on with the gastrointestinal involvement. I have already mentioned the proctoscopy. To me that gives support to the diagnosis of ulcerative colitis.

We might see the x-ray films. I think the degree of distention of the stomach and intestinal tract is somewhat unusual. It makes me wonder if anything else ought to be considered with involvement of the gastrointestinal tract. I assume, however, that the distention was secondary to the colitis. I am interested also in the size of the liver and spleen.

DR STANLEY M WYMAN. The plain film of the abdomen shows the liver margin, and there is no evidence of gross change in the size of the liver. The lower margin of the spleen comes down an approximately normal distance. If anything, the spleen is slightly larger than usual. This is far from definite. The films of the colon show an extensive, finely granular ulcerating process, which begins in the rectum and extends throughout the entire length of the colon up to and involving the cecum. This is characterized by multiple, very tiny, spicule-like ulcerations, and the wall of the bowel appears to be thickened, suggesting that the process may have been going on some time. We have another plain film of the abdomen taken six months after the first, and there is a suggestion of an over-all, hazv density to this abdomen that raises, as Dr Ropes suggests, the possibility of fluid in the peritoneal cavity. I am not familiar with the technique employed on this film, which was made in another hospital, and perhaps that is a dangerous statement to make. The last film taken in this hospital is a portable grid film and shows the stomach filled with gas and rather large. It also shows, as the record states, gas in the transverse colon and some in the ascending and descending colon.

DR CHESTER M JONES. Any fluid?

DR WYMAN. I cannot make a statement because this film is inadequate.

DR ROPES. Surely the x-ray films are more than corroborative of a very severe ulcerative process in the colon of long duration. We know that she had it severely for two years and had some disease in the colon for four years. I am somewhat surprised at the degree of distention on admission and later the marked distention and stopping of peristalsis. I wondered at first whether or not she had had a perforation, but in the absence of other indicative signs I think it is unlikely and will assume that the distention and ileus were merely associated with the diffuse inflammatory disease.

The rest of the course following admission is, to my mind, a combination of the already present ulcerative colitis, with its severe constitutional reaction, and involvement of liver with apparent liver failure, and then some degree of renal failure. The convulsions occurring near the end were probably due to tetany. The calcium was 6.5 mg per 100 cc on the following day. We are not given the phosphorus values, and unfortunately we know too little about the urinary situation to say whether the tetany was due in part to renal involvement. It could have been due to the long-continued diarrhea, loss of vitamin D and loss of calcium over a long period, and may have been only secondary to the colonic disease. The convulsion was relieved rather rapidly with calcium, which is some corroborative evidence that it was due to tetany. It is true that the total protein was somewhat low, being under 6 gm per 100 cc, but if one adds another milligram to the calcium, it is still at a level at which we can assume that the ionic calcium was low enough to produce tetany.

The two other systems involved have to be considered separately at first. The liver was certainly involved. I should think there were only two possibilities that would relate the liver to the colonic disease. One is the liver disease associated with ulcerative colitis. As far as I know there is as yet no indication how they are related or what the etiology of the liver involvement is. It apparently varies in type. In this case the terminal course, I think, was due in large degree to liver failure. We have relatively little evidence whether or not there was any cirrhosis associated. I do not think that it could be diagnosed definitely from the available evidence, although it could not be ruled out.

The other possibility is to consider the presence of amyloidosis, which does occasionally occur in ulcerative colitis. Not too long ago a case was presented here with ulcerative colitis and associated amyloidosis. However, in the presence of both liver and renal involvement from amyloid I think it would be very unusual to have such a predominance of liver failure due to amyloid disease. Liver failure with amyloidosis has been reported and does occur but much less commonly than renal failure from amyloidosis.

Renal involvement was also definite. It may have been associated chiefly with a bleeding tendency, which was so apparent elsewhere, or the renal failure may have been secondary to the patient's general condition. On the other hand, with the information available I cannot rule out some primary renal involvement. I am unable to relate any renal involvement to disease of the colon unless it was due to bleeding or to amyloidosis.

In considering the underlying etiology of the whole picture there is little or nothing to suggest that any part was due to a neoplastic process. The majority of infectious processes can be ruled out.

The whole picture cannot be explained by tuberculosis. The colonic picture would be unlikely, and any such degree of liver involvement would be rare if not unheard of. I cannot rule out parasitic disease, but even if this were amebic colitis, which I doubt, the liver involvement would be an unusual form of amebic liver disease.

I believe that the best explanation is chronic idiopathic ulcerative colitis, with some unusual features, and the liver disease is that found in association with ulcerative colitis. The second most likely possibility is amyloidosis, explaining the liver and renal involvement secondary to what I consider ulcerative colitis.

DR DANIEL S. ELLIS: This patient was admitted with a diagnosis of ulcerative colitis, and she was so sick for the first two days that we did not immediately become aware of her liver involvement. As we began to get more and more of the story and to see her reaction and rapid deterioration it became apparent that we were dealing with liver failure and presumably cirrhosis of the liver, secondary to the ulcerative colitis.

DR JONES: I think one very interesting point was the terminal phase of the disease—the very striking acidosis that developed, with extreme Kussmaul breathing. I saw the patient several times with Dr. Ellis and I think this was one of the striking events in the last forty-eight hours—at least I would say she was practically comatose and breathing in a manner much like a diabetic person in deep acidosis. That was something I had not seen before that I can recall, at least to such a striking degree, in this type of combined inability of the liver and kidneys to work properly. One thing rather interesting, and I think it is probably a correct observation, was the sudden appearance of spider angiomas. I do not think she presented them when she came in.

DR ELLIS: This is hard to say. We did not even realize she was jaundiced when she came in. She was in a dark room, and not until we moved her to another room was the jaundice discovered. The situation in the abdomen during the first three days, as Dr. Ropes mentioned, made us wonder if she had intestinal perforation. She became more and more distended. Part of the distention we thought was due to medication. We asked Dr. McKittrick to see the patient since we felt we needed surgical advice. We could not be sure that she did not have an emergency within the abdomen.

DR TRACY B. MALLORY: I was impressed with the apparently sudden reversal of the albumin-globulin ratio in four or five days. I checked the figures with those in the record, and they are correct. I had never supposed it was possible.

DR JONES: I wondered about that.

DR ELLIS: Those are the correct figures. The only way we could explain it was on the basis of transfusions. She was well bled out. She had three

transfusions in twenty-four hours, and the second albumin figures were taken immediately after that.

DR JONES: What you pointed out is interesting and I think it all goes together. As I have already said, the sudden appearance of spider angiomas was very striking, and she did have a rapid and very dramatic deterioration of liver function and the drop in albumin may have reflected in part the loss of liver function as it progressed very rapidly.

Another striking thing was the sharp drop in sodium. This was replaced to a certain degree but we were never able to catch up. It dropped from 136 to 120 milliequiv per liter. There was almost a chemical upheaval in the whole picture. I suspect that the liver deteriorated very rapidly in a matter of a few days after having been about in balance for a long time.

DR LELAND S. MCKITTRICK: I have little to contribute because my decisions were very simple. In the first place, I do not think it possible to tell with accuracy whether or not perforation has occurred in a patient with ulcerative colitis. We have seen these patients with peritonitis from perforations when we could not tell when the perforation had occurred. She was very distended, and the first time I saw her she was slightly resistant and tender on the left side, but fortunately for any decision on my part, her general picture was such that one was not concerned about any surgical interference. It was obvious that her problem was not ulcerative colitis alone. This woman was sick from something else, and after these first few days it became reasonably apparent what that something else was. I have not seen, but perhaps Dr. Jones, Ellis or Ropes has, a patient with ulcerative colitis in whom the process in the liver was so precipitous and went on so rapidly as it did with this patient. This was almost like the liver deaths after an operation in the rapidity with which it moved along.

DR JONES: That is right. The picture that we used to see with acute yellow atrophy.

DR MCKITTRICK: And the so-called hepatorenal syndrome after surgery.

DR JACOB LERMAN: I should like to ask Dr. Wyman if the x-ray picture is consistent with amebic ulceration.

DR WYMAN: There is no specific characteristic picture of amebic ulcerations. This is more consistent, in my mind, with simple idiopathic ulcerative colitis.

CLINICAL DIAGNOSES

Ulcerative colitis, universal, chronic
Cholemia
Cirrhosis of liver
Cerebral hemorrhage?

DR ROPES'S DIAGNOSES

Ulcerative colitis, with associated liver involvement.
Cirrhosis of liver?

ANATOMICAL DIAGNOSES

Ulcerative colitis chronic
Cirrhosis of liver, post-atrophy type
Acute necrosis of liver, focal, disseminated
Pulmonary edema
Bronchopneumonia, bilateral
Anasarca

PATHOLOGICAL DISCUSSION

DR MALLORY: Autopsy showed an ulcerative colitis involving the whole bowel. Three liters of fluid was found in the peritoneal cavity, and the liver was small, grossly nodular and a little flaccid, but quite tough—very obviously a cirrhotic process. The nodules of regeneration ranged from 2 to 8 mm in diameter, a wider range than one usually sees in the common type of fatty, so-called alcoholic cirrhosis. The nodules of liver parenchyma were sharply circumscribed and embedded in large and extensive areas of scarring in which many bile ducts were present. There were also, at the edges of these nodules, hemorrhagic extravasation and fresh necrosis of liver cells. So I think we can classify this cirrhosis without any question as the post-necrotic type that follows a healed atrophy, and there was also evidence of the recurrence of that process in the form of fresh, massive necrosis just within the last few days before death. There was severe, terminal, pulmonary edema and bronchopneumonia.

This development of liver disease in association with ulcerative colitis is of considerable interest and, as Dr. Ropes has pointed out, not very much is known about it. Four out of five patients dying of ulcerative colitis show at autopsy a massive, fatty infiltration of the liver, and an occasional case will show diffuse, fatty cirrhosis, essentially similar to that seen in chronic alcoholism. This is the other type of portal cirrhosis that appears to follow an attack of massive atrophy. Himsworth and Glynn,* in the last four or five years, have made the claim that post-necrotic cirrhosis can result from dietary deficiency. A good many people who have attempted to repeat their experiments have had very little success in so doing, and it is very difficult to find any distinct proof in the field of human pathology that atrophy of the liver has resulted from dietary insufficiency. A case of this sort might be cited as evidence, but there are so many other factors—for instance, the strong element of infection and multiplicity of drugs with which she was treated—that it is inconclusive.

DR JONES: What did the kidneys show?

DR MALLORY: As far as we could tell, they were essentially normal, slight dilatation was noted in Bowman's capsule and minimal, if any, changes

*Himsworth H. P., and Glynn L. E. Massive hepatic necrosis and diffuse hepatocytolysis (acute yellow atrophy and portal cirrhosis) their production by means of diet. *Clin. Sc.* 5:93-125, 1944.

in the tubules. So I think that the renal insufficiency was secondary to the liver condition.

DR JONES: Do you think that is the case in the hepatorenal syndrome? A certain group have kidney damage, but a great many show evidence of inadequate renal function in relation to hepatic failure.

DR ELLIS: Was the brain examined?

DR MALLORY: Yes, and it was normal.

CASE 35102

PRESENTATION OF CASE

A twenty-nine-year-old man was transferred to this hospital because of diarrhea and jaundice.

Since the age of fourteen he had suffered recurrent bouts of frequent loose stools. Approximately two years before entry he was treated by his physician over a period of three months because of nausea, headache and slight increase in diarrhea. At the end of this time it was noticed that he was jaundiced and that the urine was dark. There was loss of weight and appetite, and the liver was large and tender. He improved and returned to work, but one month later he was found to have anemia, for which he was given transfusions. The weight had fallen from 160 to 140 pounds, and there were signs of fluid in the right side of the chest. The liver edge was palpable three fingerbreadths below the costal margin. The temperature was 99°F. There was no jaundice, ascites or peripheral edema. He was instructed concerning a high-protein, high-carbohydrate diet and rest and, although he was advised to return more frequently to his physician, he was not seen again until about six weeks later, when, aside from a 15-pound weight gain, physical findings were essentially unchanged.

He returned to work for two and a half months when, following an attack of gastroenteritis, diarrhea became very severe. Again, a macrocytic anemia required several transfusions. During the next six months he became progressively worse and was finally admitted to another hospital. At this time he was semidelirious, and the temperature was 104.5°F. Gynecomastia, spider nevi and superficial abdominal varices were present. Sigmoidoscopy revealed diffuse petechial ulcerations and edema of the sigmoid and rectal mucosa. There was slight contracture of the mucous membrane in one area, and polypoid changes were noted in the sigmoid. The feces showed no enteric pathogens or parasites. There was 50 per cent retention of bromsulfalein, the serum van den Bergh showed a delayed positive reaction, and the prothrombin time was 45 per cent of normal.

In the hospital he was given transfusions, sulfasuxidine, penicillin and a high-protein, high-carbohydrate diet. Three months later he was admitted to another hospital, where on physical examina-

tion he was found to have a right hydrothorax, ascites, jaundice and a temperature of 102.6°F. The white-cell count was never above 4200, and neutrophils were never over 26 per cent. The total protein was 6.1 gm, with an albumin of 2 gm and a globulin of 4.1 gm per 100 cc. A bromsulfalein test showed 35 per cent of the dye retained in thirty minutes. Under a regimen of rutin, vitamin K, streptomycin, crude liver extract, vitamins and high-protein, high-carbohydrate diet he did well. The fever and jaundice disappeared, the ascites and hydrothorax became less marked, and appetite improved. Against the advice of his physician the patient was discharged after three weeks in the hospital. He had barely returned home, however, when diarrhea became very marked. Within a few days the temperature rose to 104°F, and he was disoriented. Five weeks later he was readmitted to the same hospital, where, with the exception of jaundice, he exhibited the physical findings of the previous admission but to a much greater degree. In addition to the previous therapy, intravenous albumin and mercurhydrin were administered. The course, however, was progressively downhill. Repeated thoracenteses, with the removal of 2000 or 3000 cc of yellow fluid, were necessary. Never a co-operative patient, he became even less so, refused food and fluids, and cursed and struck the nurses. For one week he was psychotic and unresponsive. Stools usually averaged four to eight daily, but at times there were ten to fifteen per day, with or without blood, although there was never any great loss of blood. At the end of two and a half months it was impossible to obtain nurses for him and practically impossible to treat him because he refused all forms of medication.

A history, later obtained from the patient's father, disclosed that his parents had been divorced for many years and that his marriage had also been unsatisfactory, a separation having taken place six months before admission. Apparently the patient was a headstrong person, and it was noted that arguments with the family were often followed by bouts of diarrhea. He did not drink alcoholic beverages.

On admission to this hospital physical examination revealed a semicomatose, emaciated, chronically and critically ill young man lying quietly in bed and occasionally groaning or crying out. There was clubbing of the fingers and dullness to flatness over the right chest. The cardiac impulse was forceful and diffuse, and the liver edge was palpated two or three fingerbreadths below the costal margin. Gynecomastia and testicular atrophy were present. There was no jaundice or peripheral edema.

The temperature was 99°F, the pulse 120, and the respirations 27. The blood pressure was 88 systolic, 55 diastolic.

The urine gave a + test for albumin, and the sediment was loaded with red blood cells. The

blood hemoglobin was 10.5 gm, the white-cell count was 4200, with 23 per cent neutrophils, 58 per cent lymphocytes, 12 per cent monocytes and 2 per cent eosinophils. The red blood cells showed moderate variations in size, and the platelets were normal. The serum protein was 6.5 gm per 100 cc, with 2.5 gm of albumin and 4.02 gm of globulin, and the albumin-globulin ratio was 0.6. The non-protein nitrogen was 23 mg per 100 cc, the chloride was 101, the sodium 131.4 and the potassium 3.9 milliequiv per liter. A cephalin flocculation test was ++ in twenty-four hours and ++++ in forty-eight hours. The prothrombin time was 27 seconds (normal, 16 seconds). The stools were light tan and guaiac negative.

During the first hospital week the patient remained critically ill despite frequent transfusions, intravenous albumin, streptomycin, mercurhydride and other supportive therapy. During brief periods of consciousness he was most resistant to anything being done for him. Most of the time he was irrational, semicomatose or in frank coma. Proctoscopy revealed scattered polyps and a granular mucosa, which bled profusely on the slightest trauma. A biopsy of one of the polyps was later reported as pseudopolyp and chronic ulcerative colitis. During the next several days he showed considerable improvement to such a degree that on the evening of the fourteenth hospital day he read magazines and talked about future plans. On the following day an ileostomy was performed. Postoperatively he did fairly well until the third day, when he complained more severely of abdominal pain. On physical examination he was irrational and had grunting respiration. The ileostomy, which had more recently drained poorly, was found prolapsed but still viable. There was abdominal distention, a fluid wave and absent peristalsis. The right side of the chest showed more fluid than before. The temperature was 103.5°F. The blood hemoglobin was 10.5 gm, the white-cell count was 3800. The blood sodium was 132.2, the chloride 96, the potassium 3 and the carbon dioxide 27.9 milliequiv per liter. Jaundice and peripheral edema became marked, and the left side of the chest, which had been clear all during hospitalization, showed many rales. He remained in coma with gasping respirations and was found dead in bed on the fourteenth postoperative day.

Throughout the patient's stay in the hospital the urine showed + or ++ test for albumin, and the sediment contained 15 to 30 red blood cells and 3 to 5 white blood cells per high-power field. The highest white-cell count recorded was 6500, and most counts were in the range of 3600. Therapy consisted of transfusions, intravenous fluids, streptomycin, penicillin, ampicillin and other supportive measures. There was excellent response to the several injections of mercurhydride given. Repeated paracenteses were of little benefit.

DIFFERENTIAL DIAGNOSIS

DR REED HARWOOD From the onset of the jaundice to the time of death it was evident that this patient had two severe diseases—the disease of the colon and that of the liver. I think the history of the last two years merely records the downhill course and progress of these two diseases, with each making the other worse. We are told very little about the onset. I shall try to reconstruct what may have happened at that time.

I imagine that the physician taking care of him saw him at home, and that the patient had vague complaints. The doctor was not quite sure what part of the body was involved or what the diagnosis was. I would guess that he paid most attention to the diarrhea—he probably gave the usual mild, supportive measures for the diarrhea and did not realize that he was dealing with something extremely serious until the jaundice appeared. He then looked back and wondered what was the cause of the jaundice. Here are the possibilities that occurred to me, not listed in the order of probability but as I thought of them. Virus hepatitis. Perhaps these vague complaints of headache, nausea and anorexia represent mild hepatitis, with little or no jaundice. Virus hepatitis can relapse and perhaps at the end of two or three months, with his poor nutritional state from diarrhea, he had an exacerbation during which the jaundice developed. Toxic hepatitis of some sort is another possibility. Such chemicals as cinchophen, sulfonamides, anti-amebic medication or possibly some industrial solvent to which he had been exposed may have been responsible. I wondered also whether ulcerative colitis could produce such severe liver failure. I decided that it probably did not in this case. From the history we do not get the impression that he had a severe ulcerative colitis or that he was in a severely depleted state at the time the jaundice developed.

Then, of course, I thought of amebiasis as an explanation for the whole picture. We know that amebiasis will cause diarrhea, we know that amebas can invade the liver, where they cause a severe hepatitis, and also that amebic abscess can rupture from the liver through the diaphragm into the lung. But from all I can find out about amebic hepatitis, it does not fit the picture here. Amebic hepatitis is a severe disease, the patient is acutely ill, with a high fever and a high white-cell count. The same statement can be made of amebic abscess in the lung. I am sure this patient would have been sent to the hospital if he had such alarming manifestations. Although I cannot rule it out, I am quite confident that amebic hepatitis will not be found. So we come to the conclusion that we are dealing with two diseases—chronic idiopathic ulcerative colitis and hepatitis with cirrhosis, probably the coarsely nodular type of cirrhosis, with the etiology of the hepatitis undetermined.

Several details of this case warrant brief comment. The appearance of the hydrothorax one year

before the ascites puzzled me. I cannot attempt to explain it. Another point that bothered me was the low white-cell count, the granulocytopenia in the face of severe sepsis in the terminal stages. I find difficult to explain. It may be that as a result of chronic, wasting disease, the bone marrow was depressed. Possibly the granulocytopenia was due to drugs. He must have had a great many different kinds of drugs. Perhaps the sulfonamides were responsible. I thought of some blood dyscrasia such as leukemia but ruled it out. Then there was the testicular atrophy, the low blood pressure and the low blood sodium, all of which made me wonder if that combination could be added up to adrenal failure. The hematuria I ascribed to the prothrombin deficiency. I considered other diseases, including amyloid disease, tuberculosis and cancer of the liver or bowel, and decided that they did not play an important part. As for the final episode, one cannot say whether or not he had a perforation with peritonitis toward the end. I think it is very likely that he had bronchopneumonia.

DR J. H. MEANS: I think the endocrine part of the disease is interesting. He had gynecomastia and testicular atrophy. I would be interested in knowing about the pubic, axillary and body hair in relation to liver disease. There is nothing about that in the abstract.

DR DANIEL S. ELLIS: They were quite normal.

DR MEANS: What causes these signs when they do occur? Is it because the liver does not bring down estrin normally?

DR ELLIS: I do not know, but that is one of the theories.

When this patient was admitted we knew he had liver disease. The liver was palpable, and everyone thought it was nodular. We thought we were dealing with advanced cirrhosis to begin with and considered the question of how much one could salvage and whether one should attempt to operate on him as a supportive measure. An ileostomy was performed, and the liver did not have enough reserve to make the grade, and we thought his death was primarily that of liver failure.

CLINICAL DIAGNOSES

Chronic ulcerative colitis
Cirrhosis of liver

DR HARWOOD'S DIAGNOSES

Chronic idiopathic ulcerative colitis
Hepatitis, with coarsely nodular cirrhosis

ANATOMICAL DIAGNOSES

Chronic ulcerative colitis, with pseudopolypoidosis and adenocarcinoma
Portal cirrhosis of liver, post-atrophy type
Ascites
Operation ileostomy
Intussusception, with gangrene of terminal ileum

PATHOLOGICAL DISCUSSION

DR TRACY B. MALLORY: Autopsy on this man showed a liver within normal weight limits, 1700 gm, but coarsely nodular, with some of the nodules measuring 15 mm in diameter. This microscopical preparation shows one of the relatively large areas of regeneration and here a wide band of scar tissue. Most of the nodules of liver cells are sharply outlined as if encapsulated, and there is no invasion of fibrous tissue into the periphery.

There was in this case no clear-cut terminal necrosis. There was extensive ascites, 5000 cc, and an unusual complication of the last few days of life was an intussusception of the distal end of the ileum beyond where it had been transected to form the ileostomy. Finally there was incipient peritonitis.

This is obviously another case of post-necrotic type of cirrhosis. One additional etiologic factor in this case was the suggestive history of epidemic hepatitis. In retrospect one cannot say it was or was not, it might have been.

DR CHESTER M. JONES: I am sorry that Dr McKittick is not here to comment on the ileostomy. At the time it was perfectly obvious that if the patient was to be helped at all, ileostomy had to be done, but it was impossible to arrive at a point when the patient would tolerate any such maneuver. When he came in it was quite obvious that he was desperately sick. It seemed we had to take the chance to make a situation whereby the ulcerative colitis and nutrition could be controlled and, by so doing, possibly to be able to stop the progression of the process in the liver long enough to get him in some sort of decent condition—obviously, a desperate move. Everyone realized it and did not expect to get away with it.

DR ALFRED KRANES: What was the colon like?

DR MALLORY: It showed a severe, chronic, ulcerative colitis with marked polyp formation. We see three kinds of polyps in patients with longstanding ulcerative colitis. Some of them are mostly inflammatory in character and are called pseudopolyps—a sort of hypertrophy of the remaining fragments of mucous membrane. We sometimes see true neoplastic polyps, and in some cases frank carcinoma develops. The biopsy on this patient we reported as a pseudopolyp, and at autopsy sections were taken from two or three other lesions by hazard, one of which proved to be carcinomatous. So nothing less than a total colectomy would have helped him for very long.

DR HARWOOD: How about the adrenal glands? Did they show anything?

DR MALLORY: No.

DR JONES: I think it is important to point out that patients with ulcerative colitis going a good many years, more than ten years, run a definite hazard of developing carcinoma. It is often impossible to be certain about this diagnosis because the blood in the stools is assumed to be due to the colitis.

MASSACHUSETTS FIVE-YEAR PLAN

MORE than 600 panel participants and delegates from a number of representative organizations met together in the first Massachusetts Health Conference, held at the Hotel Statler on February 19 and 20 for the purpose of discussing means of improving health in Massachusetts during the next five years. Agencies represented ranged from the Ladies Garment Workers Union to the Junior League and from the Massachusetts State Nurses Association to the Committee for the Nation's Health.

Nineteen panels were conducted, the majority of them holding sessions both morning and afternoon on the Saturday and Sunday of the Conference. Such topics were fruitfully discussed as

accidents and their prevention, citizen participation in state and community planning, dental health, environmental sanitation, health problems of the aged, hospital problems, industrial health, maternal and child health, medical-care costs and methods, mental health, nursing problems, rural health problems and school health, and others of no less importance.

At luncheon on the first day Dr Clifton T. Perkins, Commissioner of Mental Health, told of the problems of his department and the opportunity that an increased budget and improved personnel will give for the transformation of its objectives from custodial care to active treatment and the prevention of mental disease. In the evening the Hon. John F. Kennedy, congressman from the eleventh Massachusetts District, addressed the dinner audience, and at luncheon on the following day Dr Charles F. Wilensky, president of the American Public Health Association, and His Excellency, Governor Paul A. Dever, spoke to the Conference. Dever announced in particular that the first claim considered by him of all those made for state funds was for the physically and mentally ill citizens of the Commonwealth.

As the report of each panel chairman was made at the close of the Conference, the result of the co-operative and constructive discussion that each problem had received became evident and the contributions that could be made by lay as well as professional participants. Of special interest were the meetings of the most largely attended group, that on medical-care costs and methods, under the chairmanship of Dr. Hugh R. Leavell, professor of public-health practice of the Harvard School of Public Health.

Discussers in the field covered by this panel varied from representatives of the Department of Public Health and the Massachusetts Medical Society to those from Blue Shield, the Committee for the Nation's Health and the CIO. Agreement on all particulars was naturally impossible, but discussion was free, frank and friendly. The steering committee of the panel in its final statement approved making adequate medical care "available to everybody, regardless of income, race, color, creed or national origin," the term to include the

VETERANS ADMINISTRATION HOSPITAL PROGRAM

THERE has been considerable confusion about the treatment not only of disabled veterans and their dependents but also of those suffering from nonservice-connected disabilities or illness. As a recent release from the Veterans Administration states, many wives and families of veterans were treated by Army and Navy doctors, while their husbands were on active duty, as a result of what is almost a service tradition. For many years, families of personnel in the armed forces obtained treatment from Army or Navy physicians if it were "more practical" for such service to be rendered by these physicians. Some wives now erroneously believe that they are also entitled to medical treatment from Veterans Administration physicians.

Men and women who served in the armed forces, except those with dishonorable discharge, are entitled to hospital treatment in the following categories: emergency cases, those suffering from injuries or diseases incurred in or aggravated by military service, and those who state under oath that they are unable to pay hospital charge for treatment of nonservice-connected disabilities or illnesses. Veterans in the last classification, if not in the emergency class, must wait until a bed becomes available. Treatment is available for veterans with service-connected disabilities, but in other cases each veteran's eligibility must be determined by the Veterans Administration itself before treatment of this type can be authorized.

These limitations are of considerable interest in view of the prospective hospital expansion program, which may be used as a political argument to spend more of the taxpayers' money wastefully and ill-advisedly. Studies in the past three years have

indicated a need for a change in this program, the estimated requirements for hospital beds made during and immediately after the war were considerably larger than has proved necessary. Admission policies have been such that more than two out of three patients were and still are admitted to hospitals for nonservice-connected ailments.

As a result of the careful studies of 64 individual projects not yet under contract, the President has ordered a reduction of 16,000 beds. To effect this, the Veterans Administration plans the cancellation of 24 proposed new hospitals and reduction in the size of 14 others, a change in program that "will not result in a single service-connected veteran being denied immediate hospitalization."

There is another factor. Owing to the shortage of professional personnel, the Veterans Administration is having great difficulty in properly staffing its present hospitals. The estimated maximum load of patients with *service-connected* disabilities is about 51,000, which even at present, leaves more than twice as many additional beds available to the other veteran patients. "In the light of more than three years' experience since the end of World War II," according to the release, "it is evident that the estimates of bed requirements were considerably too high. To construct new hospitals which we cannot staff and therefore, cannot put into use would be an indefensible waste of public monies."

This report states further that the proposed elimination of new beds would result in a saving of \$280,000,000. With many hospitals running at a prohibitive annual deficit, it seems that the medical profession has here a splendid opportunity to exert its influence in constructive suggestions that will help to relieve the present critical condition of some civilian hospitals in which nonservice-connected cases should be cared for, but at the same time, steps should be taken to ensure that the care given for *service-connected* injuries and illnesses of the veteran remains the best that can be obtained.

FIRST BOOK ON RICKETS

DANIEL WHISTLER, an Englishman, in 1645, presented to the University of Leiden for the degree of doctor in medicine a dissertation entitled *De*

services of "physicians, dentists, pharmacists, nurses, medical social workers and other professional persons, the services of clinics, hospitals and related facilities and the supply of necessary drugs and appliances"

The use of voluntary prepayment group health plans was encouraged, it was admitted that the people have also the right, "if they deem it wise," to establish a system of governmental health insurance. A resolution was passed unanimously disapproving the senseless slaughter of "tens of thousands of unwanted animals in public pounds," when they were so desperately needed for medical research.

It may fairly be said that the success of the Conference exceeded the fondest hopes of its sponsors, improved relations and better understanding of mutual goals by diverse interests should result

BENJAMIN RUSH AND HIS TRAVELS THROUGH LIFE

IN 1800, Benjamin Rush, the energetic, quarrelsome physician and patriot of the American Revolution, then fifty-five years of age, began to write his autobiography, *Travels through Life*, having just seen through the press his *Essays, Literary, Moral, and Philosophical*. His active and exciting life brought him many memories of his student days, early years of practice in Philadelphia, the Revolution and his part in the Declaration of Independence, his bitter fight for reform in the military hospitals, the yellow-fever epidemic of 1793, and his battle with William Cobbett, then subsiding after Cobbett's departure from America in June, 1800. *The Rush Light*, a harsh pamphlet published by Cobbett, was rapidly dimming, and Rush could turn to a calmer period of reflection, practice and the teaching of medicine, all gifts with which he was highly endowed, and to his account of his private life. His written word, long in manuscript or imperfectly printed, has now been issued in a complete and unexpurgated edition under the meticulous and scholarly hand of George W. Corner, along with the "Commonplace Books" or diaries for 1789-1813.¹

First taught in 1761 as a private pupil of John Redman, Rush later attended the lectures of Shippen and Morgan from 1762 to 1765, when the school of medicine of the University of Pennsylvania was in its infancy. He went abroad in 1766, listened to lectures in Edinburgh, brushed up on his Latin, taught himself Italian and Spanish, and received his medical degree two years later. After further training in St. Thomas's Hospital in London and a visit to Paris, Rush returned to Philadelphia in 1769, developed a successful practice, advocated the abolition of slavery, became an active patriot with Thomas Paine, John Adams and Thomas Jefferson, signed the Declaration, served for a short and stormy period as surgeon-general of the armies of the Middle Department, lectured at the medical school and, after 1789, devoted himself primarily to his profession. Basing his views on those of William Cullen and John Brown, he developed a "system" of treatment, calling for "depletion" by thorough bleeding and purging, a theory that came to hold for his speculative mind all the fascination of an ultimate panacea. When his method was applied in the yellow-fever epidemic, Rush claimed superior effectiveness, but he failed to keep exact records of his own cases and he did not even use the vital statistics of his day. Cobbett, a lay critic, soon discovered the weakness of Rush's treatment, and, although Rush was not guilty of deliberate misrepresentation, a modern evaluation of his work indicates that he was "rather the victim of a certain credulity about diagnoses and cures which characterized much of his work."² He was, in other words, an observant man, but not a good observer.

Rush's autobiography is not a very readable volume, but factually it is an outstanding record of his times, a "Philadelphia Story" of distinctive merit, clearly told, without retraction or hesitation. Of his medical enemies he speaks with no malice, for he was at heart a lover of peace and of his fellow citizens.

The numerous footnotes by Corner are authoritative and always helpful, the index is fully adequate, and the book is a great credit to the American Philosophical Society, the holder of the original manuscript, and its able editor, in whose

CROKE—Louis W. Croke, M.D., of Dorchester, died on February 15. He was in his sixty-fourth year.

Dr. Croke received his degree from Tufts College Medical School in 1911. He was formerly staff surgeon for Liberty Mutual Insurance Company and was a fellow of the American Medical Association.

A sister survives.

NOTES FROM THE MEDICAL EXAMINER

BARBITURATE TOXICITY

The rapid and accurate quantitation of barbiturates in blood and tissue has been made feasible in the past three years by the development of methods utilizing the ultraviolet spectrophotometer.^{1,2} These require only 5 to 10 cc of specimen, and it is possible for the first time to determine the blood barbiturate concentration of a comatose patient in the emergency room as well as that of a dead person whose residual concentration is very low.

CORRELATION OF BARBITURATE LEVEL WITH STATE OF CONSCIOUSNESS

Preliminary studies of the concentration of pentothal in the blood during surgical anesthesia³ show that consciousness is lost at about 1.0 mg per 100 cc, whereas second-plane anesthesia is reached at 2.0 to above 3.0 mg per 100 cc.

The short-acting barbiturates, seconal, amytal and pentobarbital, cause coma when the blood level is between 1.0 and 3.2 mg per 100 cc. Consciousness is lost at slightly lower levels when larger doses are ingested—that is, with rapidly rising drug concentrations in the blood. Another important modifying factor is the state of reflex excitability of the central nervous system; a given blood concentration is less depressing in agitated patients or those stimulated by benzedrine or caffeine.

The long-acting barbiturates, barbital and phenobarbital, are much less potent than those mentioned above. Several conscious patients, some of whom were ambulatory, were found to have blood levels as high as 5.0 to 7.5 mg per 100 cc. Two patients with blood phenobarbital levels of 7.2 and 6.8 mg per 100 cc were described clinically as semicomatose. The minimum blood barbiturate concentrations accompanied by coma in 7 patients who recovered from barbital or phenobarbital poisoning were in the range 7.0 to 12.0 mg per 100 cc.^{4,5}

FATAL CONCENTRATIONS OF BARBITURATE

In the evaluation of a post-mortem blood barbiturate level as the cause of death five principal variables must be considered. These are the identity (potency) of the barbiturate concerned, the time elapsed from ingestion of the drug until death, the presence of concomitant alcoholism or central-nervous-system depression by other agents, the effects of therapy and complications of which

respiratory infections and renal failure are particularly noteworthy.

The higher potency of the short-acting barbiturates, as compared to barbital and phenobarbital, is well exemplified in a series of 10 cases, all fatal without therapy and none complicated by alcoholism.^{4,6} Seven deaths resulted from poisoning by seconal, pentobarbital, amytal or combinations of these agents. The post-mortem blood barbiturate concentrations were 2.0, 3.7, 4.0, 4.8, 6.6, 7.2 and 7.5 mg per 100 cc. The others were phenobarbital and barbital poisoning, and the levels were 9.8, 12.0 and 34.0 mg per 100 cc. It should not be inferred, however, that the finding after death of a blood barbiturate concentration of 2.0 mg per 100 cc of a short-acting or of 9.8 mg of a long-acting barbiturate constitutes *prima facie* evidence of death from barbiturate poisoning. Recovery has been observed after barbiturate levels of 5.1 mg of pentobarbital, 12.8 mg of phenobarbital and 20.6 mg per 100 cc of barbital.

The time factor is of importance in two respects. Death may occur in the early hours of barbiturate poisoning with relatively low blood levels of the drug if the concentration is rising rapidly. In the first case of the short-acting series cited above, death occurred within four hours of ingestion of the drug with over 65 gr (4.3 gm) of seconal still in the stomach. On the other hand, barbiturates share with carbon monoxide and alcohol the property of producing irreversible asphyxial damage to the brain and then being partly or completely destroyed or excreted before death ensues. One young woman succumbed five days after ingesting a fatal dose of seconal although no barbiturate was demonstrable in the blood on the third day.

Experimental and clinical evidence of a "synergistic toxic action" of barbiturates and alcohol has been published,^{7,8} but the dangers inherent in indiscriminate use of combinations of these agents deserve re-emphasis. Seven deaths due to the combination of alcohol and barbiturate, although neither drug was present in ordinarily fatal concentrations, have been encountered in recent years by members of the Department of Legal Medicine at the Harvard Medical School. Goldbaum's⁹ terse note ("Alcoholic Died soon after injection of 100 mg of sodium amytal I.V.") is probably a further example of this kind.

Although consideration of therapy is beyond the scope of this communication it appears that general supportive therapy including oxygen, intravenous fluids to the limit of tolerance and the common stimulants are of greatest importance; picrotoxin and other convulsants should be employed with great caution lest their toxic effects be added to the barbiturate poisoning, and the use of succinate, ascorbic acid and so forth is still in the experimental stage.

morbo puerili Anglorum, quem patrio idiomate indigenae vocant "The rickets" This is the first book on the subject, and the first use of the word rickets. In 1684, Dr Whistler issued a second edition, said to be improved because of imperfections in the original example.

In 1884 Moore,¹ writing on Glisson's² treatise on rickets, published in 1650, devotes considerable space to a discussion of Whistler's small disputation and at first believed that it was not authentic and did not exist until it was called to his attention that a copy of the 1645 imprint had been discovered in the Library of the Royal College of Physicians of London.

Whistler did not lay claim to the discovery of the disease but referred to it for the first time as the rickets, a name locally applied for some twenty-five years. Moore was highly critical of Whistler and his work and brought out that Glisson and a group of co-workers had been engaged on an investigation of the disease since 1645, culminating in the publication of Glisson's book in 1650. It was intimated that Whistler rushed into print for the purpose of forestalling Glisson's book. Whistler's description of the disease is a concise and clear statement of most of the then known facts and appears to have been based on personal observations.³ Both editions are very scarce although three copies of the 1645 edition have been located in British libraries — in the British Museum, in Merton College, Oxford, and in the Royal College of Physicians, London. Likewise, there should be copies in the University of Leyden and other European libraries.

Recently the Boston Medical Library has acquired a copy of the 1684 imprint with an English translation, and a beautiful facsimile reproduction of the 1645 edition made from the copy in Merton College. The facsimile bears no indication of date or printer or that it is a reproduction, but it is known that it was done late in 1948 for Dr Alexander Cook, of Oxford, and that only a few copies were struck off for his friends. The Library is indebted for its copy to a good friend and fellow of the Library.

MASSACHUSETTS MEDICAL SOCIETY

WOMAN'S AUXILIARY

The Executive Committee of the Woman's Auxiliary of the Society held its mid-winter meeting at the Algonquin Club, 217 Commonwealth Avenue, Boston, on January 21 as luncheon guests of the President.

Present were the officers of the Auxiliary: Mrs Leighton F Johnson, president; Mrs Charles E Ayres, vice-president; Mrs John F Conlin, corresponding secretary; Mrs Andrew Nichols, III, recording secretary; Mrs Leo G Rondeau, treasurer; the presidents of the ten district auxiliaries: Mrs Oscar S Simpson, Barnstable; Mrs Curtis B Kingsbury, Bristol North; Mrs Harold R Kurth, Essex North; Mrs John J Pallotta, Essex South; Mrs Albert E Morris, Middlesex East; Mrs John F Casey, Middlesex South; Mrs George W Papen, representing Mrs J J Hepburn, Norfolk; Mrs Thomas H Lanman, Suffolk; Mrs Charles E Ayres, Worcester; Mrs William G LeBrecht and Mrs John J Curley, representing Mrs L B Thompson, Worcester North; and the chairmen of the state committees: Mrs Chester S Keefer, Education; Mrs Roger I Lee, Public Health; Mrs Howard F Root, Legislation; Mrs Reginald H Smithwick, Hospitality; Mrs John W Spellman, Benefits; and Mrs George G Bailey, Nominations. Mrs Benjamin Alexander, chairman of the Program Committee, was unable to attend.

Dr John F Conlin, director of Medical Information and Education, spoke on national legislation, outlined the plans for the Massachusetts Health Conference, and announced that an appropriation of \$500 would be requested of the Council of the Massachusetts Medical Society for the use of the Auxiliary during 1949.

Each president was asked to appoint two delegates and two alternates to attend the Health Conference. Mrs Root reported on bills affecting health that had been introduced to the General Court, and Mrs Ayres spoke about the part that the Auxiliary would take in the annual meeting of the Society in Worcester, May 25, 26 and 27.

The Auxiliary of the Worcester North District Society, organized on January 14, was welcomed to membership, and plans for a speaker's bureau were discussed.

DEATHS

BRUNELLE — Pierre Brunelle, M.D., of Lowell, died on February 11. He was in his seventy-seventh year. Dr Brunelle received his degree from McGill University Faculty of Medicine in 1896. He was a former president of the Massachusetts Medical Society and was formerly a member of the Lowell Board of Health. His widow, a son, two daughters and a sister survive.

claiming them," you are stooping to impugn the motivation of these critics without any possible justification. This is a form of *argumentum ad hominem* that can only serve to weaken the force of your remarks.

Your point that many of us members of the American Medical Association have been very negligent in the matter of taking political action at the grass roots is accurate and justified. I hope it will produce a high percentage of attendance at, and of activity in, all district-society meetings. However, when you try to shut off efforts at reform by approaches directed at higher levels, with the trite bromide that it is a dirty bird that fouls its own nest, I submit that you are descending to a low level of editorial writing.

It has been repeatedly claimed that organized medicine is democratic. I won't dispute this, but may point out that we can easily find in the world today various interpretations of the word "democratic." However, I will submit that in the American variety of democracy, free speech is one of the rights of man. The constitution of the United States abundantly protects the right of minorities to be heard.

The correspondence columns of the *Journal of the American Medical Association* should be a forum where matters of the public relations of medicine, or any other serious medical topic, could be freely discussed. It is my opinion, however, that the *Journal of the American Medical Association* does not serve this function. Apparently, it only gives space to opinions that adhere to the orthodox party line. It cannot tolerate criticism.

It distresses me to see the generally admirable *New England Journal of Medicine* bending in this direction, even if only slightly. I will go along with you that we should get busy at the grass roots, but I depart from you in your taboo of direct approaches at other levels.

If the public discovers that there is a row in the medical profession (they probably have discovered it), I believe this will be to the good. If the public know that the doctors have honest differences of opinion, I believe it is more likely to create confidence than if they look upon us as a great crowd of yes-men. After all, the public are the consumers of medical service, and have as direct an interest in, and as much right to be heard on, the problems of how medical care is to be provided, as the doctors have.

J H MEANS, M D

Boston

NOTE: Dr Means seems to have missed the point of the editorial in question, perhaps being unaware of a current type of criticism, much of it thoughtless, some of it possibly malicious, that has been directed against the American Medical Association since the assessment was announced. This applies to destructive criticism that has served no useful purpose but has, unfortunately, tended to create indecision and distrust.

It is difficult to understand Dr Means's reference to what he considers an apparent attempt on the part of the *Journal* "to shut off efforts at reform by approaches directed at higher levels." Such an accusation appears to be answered in the last paragraph of the editorial to which he takes exception, which specifically states, "If your association in your opinion is at fault then start the correction from within."

It should further be apparent to its readers that the correspondence columns of the *New England Journal of Medicine* are open to all sincere and constructive expressions of opinion, within the limits of its space — that the *Journal* is far from bending in this direction" of giving space only to opinions "that adhere to the orthodox party line."

In short, the *Journal* still maintains its belief that helpful criticism is of great value and that all sides of any controversial subject should be presented, but that little good can come of wholesale condemnation of the one organization that represents the medical fraternity in America. — Ep

CONSTRUCTIVE CRITICISM

To the Editor: In a recent issue of the *Journal* there were a number of letters voicing disapproval of the \$25 00 assessment recently passed by the House of Delegates of the American Medical Association. Some of the criticisms were justified, and some were even quite good. However in none of them were there any constructive suggestions on how better to meet the challenge. Although I am not yet a member of the American Medical Association, I have recently contributed

\$25 00 to this fund, together with my criticisms and suggestions.

It seems to me that the medical profession should have as its goal the improvement of medical care, either qualitative or quantitative, and that its members should be leaders in advocating any change, Government or private, that will improve the quality of medical care, result in better distribution of care or remove the economic hazard from illness without at the same time lowering the quality of the care. The program suggested was as follows:

PRIVATE ACTIVITIES

Expand such voluntary insurance plans as Blue Cross and Blue Shield and follow the suggestions of Dr Hawley to bring nationwide coverage to these plans.

Encourage private insurance plans, even though lay people are on the board of control, sponsored by co-operatives, industries and labor unions.

Introduce more and better public-relations systems, similar to that introduced in Colorado, with some voluntary control of fee schedules, possibly by the publication of average fees. We should tell the people about the cost of medical education and the doctor's overhead expenses.

Encourage better distribution of doctors by more rotating residencies, continued organization of and better hospital facilities for the general practitioner, and encouragement of medical students, by their teachers, to enter practice in rural communities.

GOVERNMENT ACTIVITIES

Improve and increase the public-health facilities by setting up new public-health departments in counties not now having them and expanding the public-health department's educational program.

Federal grants to finance the education of a certain number of medical students, who would agree to practice for five years in a rural community. These grants would be administered by the medical schools.

Federal aid, through the states or private insurance plans, to finance the medical care of the destitute.

A federal program to "stamp out" tuberculosis. This could be done in two distinct parts: mass chest x-ray examination by the public-health department with the aid and co-operation of local medical societies, and federal grants to the states for the construction of a sufficient number of hospitals to take care of all tuberculous patients without a waiting period and additional grants to be used for care of the patients' dependents during the time he is incapacitated by his disease.

Federal aid to the states for the adequate care of mental illnesses to be used for the construction and staffing of adequate hospitals.

Federal aid to the states for the treatment of chronic alcoholism.

It seems to me that such a program would be workable and could be administered effectively and, though expensive, would result in a worth-while improvement of the health of the nation.

J PHILIP AMBUEL, M D

904 Naval Avenue
Bremerton, Washington

THE CARE OF THE SICK

To the Editor: What is the plain nature of the crisis in which American medicine finds itself today? It is the judgment of an increasing number of people in our society that the profession is not fulfilling its ancient function of ministering to the sick as our well remembered fathers did, simply and honestly. It includes a feeling that the magnificent modern developments in the science of medicine do not filter down among the common people except through an increasingly impenetrable screen of high fees and inscrutable specialism at the top, and men of poorer quality in the highways and byways at the bottom where the people see them. In the high towers of the medical centers everyone recognizes that a high quality of medicine can be obtained for a high price and after a long wait, but who will take care of my cold, my measles or my sprained ankle, and do it reliably and well? Why is it that I must take my chances with the optometrist in my small city, or else have to wait six weeks

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

EMERGENCY MATERNITY AND INFANT CARE PROGRAM

Payment for maternity care and for care of infants under one year of age is still available under this program. However, the Massachusetts Department of Public Health is calling attention to the fact that *no authorization for payment for pediatric care rendered after April 20, 1949*, may be issued under this program.

All bills for medical and hospital care must be submitted before May 1, 1949, to Massachusetts Department of Public Health, Division of Maternal and Child Health, 73 Tremont Street, Boston.

BLUE CROSS-BLUE SHIELD

AMCP PLANS REACH SIXTY

In accepting membership applications in January from Arkansas Medical and Hospital Service, of Little Rock, Central New York Medical Plan, of Syracuse, Klamath Medical Service Bureau, of Klamath Falls, Oregon, Physicians Association of Clackamas County, Oregon City, Oregon (reinstatement), and Puerto Rico Hospital Service Association, of San Juan, Associated Medical Care Plans has increased its membership to a total of sixty plans.

This leaves only three eligible plans in active operation that are not members of AMCP, although others, now in process of organization, may soon become eligible for membership.

MISCELLANY

PHYSICIANS' WELCOME CENTER IN PARIS

Doctors from around the world who arrive in France will find a warm welcome awaiting them at the new center recently opened in Paris at 60 Boulevard de Latour-Maubourg by the French Medical Association. The center plans to give visiting physicians information on all subjects of interest to them, to arrange hospital visits and consultations and to direct attention to various scientific congresses and lectures.

As an added service to the medical profession, the French Medical Association, in conjunction with the Commissariat General au Tourisme, official Government tourist organization, will advise on travel in France and give information on hotels, restaurants, amusements and cultural activities.

The French Medical Association welcome center will be open daily from 9 to 12 and 1 30 to 6.

ARMY MEDICAL CORPS SPECIALISTS

As of January 25, 1949, 143 Regular Army Medical Corps officers and 10 civilian component officers on active duty were certified as diplomates of American Specialty Boards. This represents an increase of 51 from the date of the last published survey (September 1, 1947).

Specialists to fulfill current requirements of the Army are needed in all fields. In the specialty fields of allergy, cardiology, gastroenterology, pulmonary diseases and neurosurgery the Army still does not have a board-certified specialist, although officers are in training in each of these fields to enable them to reach eligibility for board examinations.

Commissions in the Medical Corps, both Regular Army and Reserve, up to and including the rank of lieutenant colonel, are available in these fields for qualified civilian physicians, depending upon length of professional experience and subject to Army regulations.

CORRESPONDENCE

WARNING REGARDING LITHIUM CHLORIDE

To the Editor In view of the recent deaths alleged to have been caused by the use of table-salt substitutes containing lithium chloride, and because of an increasing number of reports from physicians of observance of hitherto unexplained symptoms following administration, it is believed that an EMERGENCY WARNING should be issued to physicians, hospitals and wholesale and retail distributing outlets that products of this nature may cause injury to the users and to suggest that further prescriptions, distribution and sale be discontinued immediately, until further notice.

The United States Food and Drug Administration has taken steps toward the recall from the market of all these preparations. Superintendents of hospitals, and practicing physicians generally, are hereby requested to take the necessary measures to prevent further administration and use of these products.

CARL S. FERGUSON, *Director*

Division of Food and Drugs
Massachusetts Department of Public Health

THE RIGHT TO CRITICIZE

To the Editor Your editorial entitled "This AMA—What is it?" in the February 3 issue of the *Journal*, although it contains some truth that indeed needs saying at this juncture, also, in my opinion, displays some regrettable weaknesses.

The statement that destructive criticism "harms many and helps none" is incomplete and misleading. Destructive criticism may identify evil and pave the way to its correction. It should be followed by constructive criticism, which promotes the development of something good. In any event, we can say that destructive criticism elected Harry Truman. Whether that's for good or bad time will tell.

When you say of the critics within the ranks of medicine, "most of whom believe that they have just complaints, and derive a feeling of pleasure or sense of importance from pro-

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Psychiatry for the Pediatrician. By Hale F. Shirley, M.D., associate professor of pediatrics and psychiatry, and executive director of the Child Psychiatry Unit, Stanford University School of Medicine. 8°, cloth, 442 pp. New York: The Commonwealth Fund, 1948. \$4.50.

This book is the outgrowth of lectures given to medical students of Stanford University Medical School and likewise is a revision and expansion of a syllabus written for the clinical use of students and resident staff members of the Stanford University Hospitals. It is not intended as a complete textbook or scientific treatise, but as an introduction to the subject, and is primarily written for the medical student, the pediatrician and the general practitioner. The text has been written in simple language with emphasis on the problems frequently encountered by the pediatrician in his practice. The material has been well arranged and considers the behavior problems of children in all their aspects. The preliminary chapters discuss child guidance, development and habit training, followed by chapters on physical, intellectual, emotional, sexual and environmental factors and problems. The last two chapters have to do with the investigation and treatment of behavior problems. Lists of selected references are appended to the various chapters. A glossary concludes the text, which is printed with a good type on light, nonglare paper. There is a good index. It is a pleasure to handle this volume. It should be in all medical libraries and prove useful to pediatricians and all persons interested in child guidance.

Hemostatic Agents, with Particular Reference to Thrombin, Fibrinogen and Absorbable Cellulose. By Walter H. Seegers, M.S., Ph.D., professor of physiology, Wayne University College of Medicine, Detroit, and Elwood A. Sharp, M.D., Sc.D., director, Department of Clinical Investigation, Parke, Davis and Company, and lecturer, Department of Medicine, Wayne University College of Medicine, Detroit. 8°, cloth, 131 pp., with 27 illustrations and 9 tables. Springfield, Illinois: Charles C. Thomas, 1948. \$4.50.

This monograph on coagulants is based on developmental work conducted during the past few years by research workers. The literature of the subject is reviewed and analyzed. The bibliography appended to the text comprises 370 references to periodical articles. This valuable monograph should be in all medical libraries and in the collections of all persons interested in coagulants.

The Training of a Doctor. Report of the Medical Curriculum Committee of the British Medical Association. 8°, cloth, 151 pp. London: Butterworth and Company (Publishers), Limited, 1948. 7s. 6d.

This exhaustive report on the medical curriculum in British Universities is detailed in its recommendations. The committee's task was to consider what modifications should be made in the aim, content and structure of the medical curriculum in the light of increasing medical and educational knowledge and of the changing needs of medical practice. The summary lists 211 different recommendations. The report is divided into five parts: preliminary problems, pre-medical education, preclinical period, clinical period, and clinical curriculum. The last part, comprising nearly half the text, discusses in detail all clinical branches of the curriculum, and also includes a timetable or schedule for a seven-year course of instruction from the premedical period to internship, professional examinations and a consideration of the intern year. This valuable report should be in all deans' libraries and medical libraries and is essential to all persons interested in medical education.

Outline of Physiology. By William R. Amberson, Ph.D., professor of physiology, University of Maryland, and Dietrich C. Smith, Ph.D., associate professor of physiology, University

of Maryland. 4°, cloth, 502 pp., with 193 illustrations, by the late Norris Jones, instructor in scientific illustrating, Swarthmore College, and William Loechel. Second edition. Baltimore: Williams and Wilkins Company, 1948. \$5.00.

In this second edition of a work written principally for first-year students, much of the text has been completely rewritten, especially the chapters on the central nervous system, circulation, endocrines and reproduction. Chapters have been added on catalysis and enzymes, vitamins, sensation and the heart. The text is well printed with a good type in a two-column format. The illustrations are excellent. A comprehensive index concludes the volume.

Modern Drugs in General Practice. By Ethel Browning, M.D., Ch.B. 8°, cloth, 223 pp. Second edition. Baltimore: Williams and Wilkins Company, 1947. \$4.00.

In the new edition of this manual for the general practitioner, the author has included penicillin and has amplified the chapter on the sulfonamides. The text has been revised to include the new drugs of recognized merit. There is a chapter on thiouracil and methylthiouracil. Lists of selected references are appended to the chapters. The volume is concluded with a good index. The text was printed in Great Britain, and the publishing is good.

History of Factory and Mine Fatigue. By Ludwig Teleky, M.D. 8°, cloth, 342 pp. New York: Columbia University Press, 1948. \$4.50.

This small volume constitutes an outline of the history of industrial hygiene. The material is well organized, and the text well written. The printing has been done with a good, large type on lightweight, nonglare paper. A bibliography of 33 pages is appended to the text. A comprehensive index concludes the volume. The book is recommended for all medical and public libraries and all persons interested in the subject.

The Healthy Hunzas. By J. I. Rodale, editor of *Organic Gardening*. 8°, cloth, 263 pp., with 16 illustrations and 1 map. Emmaus, Pennsylvania: Rodale Press, 1948. \$2.75.

The Hunzas are a civilized race of people of Northwest India who are remarkably healthy and who have occupied their small domain for hundreds of years, and now number about 22,000. Living on a high plateau near Tibet, they lead a simple and isolated life. They enjoy a low percentage of morbidity. The present volume constitutes a plea for organic fertilization of the soil. The volume is well published and should prove valuable to persons interested in public health and nutrition.

Rural Health and Medical Care. By Frederick D. Mott, M.D., and Milton I. Roemer, M.D., M.P.H. 8°, cloth, 608 pp. New York: McGraw-Hill Book Company, Incorporated, 1948. \$6.50.

This new volume in the field of medical care and services constitutes a comprehensive study of the rural aspects of the subject in the United States. The various chapters discuss present-day levels and trends of rural health, physicians and other health personnel, health facilities, medical service and expenditures in rural areas, governmental services and voluntary health problems. The material is well published in every way and is concluded with a comprehensive subject index. The book is recommended to all medical and public libraries.

Biology of Pathogenic Fungi. Edited by Walter J. Nickerson, Ph.D., assistant professor of botany, Wheaton College, and lecturer in medical mycology and dermatology, Tufts College Medical School. With a foreword by J. G. Hopkins, M.D., professor of dermatology, Columbia University College of Physicians and Surgeons. 8°, cloth, 236 pp., with 47 illustrations and plates and 52 tables. Waltham, Massachusetts: Chronica Botanica Company, New York City: Stechert-Hafner, Incorporated, 1947. \$5.00.

This volume is the joint work of a number of authors and discusses some aspects of the biology, physiology and biochemistry of the fungi pathogenic to man. Extensive indexes of authors and subjects conclude the volume. The text is printed with a good type on nonglare paper. The volume is recommended for all medical, public-health and scientific libraries.

for an appointment to have my glasses checked in the big city by the great eye specialist?

Why has all this come about? I think it is partly because of a certain paranoid pride among the profession in the great teaching centers. Perfectionism has reached such a point in the great medical schools that courses on the care of the patient are a joke, a minor elective. Medical students, professors and even the great clinics are so swallowed up in the pride of scientific achievement that the patient, who should be the heart and core of medicine, has been lost somewhere among the laboratories. Give him a rarity like thrombocytopenic purpura or Addison's disease, and he becomes a distinguished medical problem, but let him have cerumen in his ears or a tonsillitis and he is scarcely worthy of the attention of the meanest medical student, or perhaps even of a technician. This attitude is sedulously drilled into the student from his first flights in anatomy until he emerges from his big-shot residency and hangs out his shingle. For eight or nine years he has studied rare diseases and excelled in solving diagnostic traps invented by his specialist instructors. Then what happens?

One of two things happens. If he has carefully played his cards, an assistantship is awaiting him right in the medical center, where he can continue his monasticism, never have to become a citizen at large, and live the rest of his life an approved monk of the inner fraternity, teaching the gospel of high-priest specialism to new generations of admiring students so that they will follow his lead. Or he may fail in his economic safeguards and have to get out into a community and scratch himself out a practice. In the jargon of the great medical center that constitutes failure. Yet always a majority of the graduates of the great schools do this. They work like beavers. They find that they have to unlearn their training, start with their discovery of the human beings they are meeting for the first time in homes and community affairs, and take care, not of rarities, but of their prevalent ailments. Nobody at the school bothered to teach much about these problems — how to handle the high-school quarterback with the sprained knee, how to console the old lady with a hemiplegia, how to command the obedient co-operation of the business man with a coronary thrombosis. These patients cannot be cured with an x-ray film or an electrocardiogram. What is to be done for the patient with rheumatoid arthritis who cannot afford a hospital? What about the cancer patient whom the surgeons have given up? How does one get care for the senile dementia, the houseful of scarlet fever or the four healthy children of the widow with virus pneumonia? Are these not problems worthy of the best medical judgment? Yet where in our professional system is the provision for care of these problems by first-rate talent?

There are plenty of graduates of substandard schools in the neighborhood, but where are the good men who will go out at night on an emergency? In many a community they are lacking. Men who should be there are sweating out their slow climb up the crowded ladder in the big city. And even there their eyes are so glued on the grinding competition of a specialty that they cannot see the crying need of good general practitioners in the city all around them. Who takes care of whooping cough, Colles fractures and epidemic diarrheas in the big city — the pediatrician, the orthopedic surgeon, and the specialist in internal medicine? At times, yes, or perhaps the hotel doctor in the next block. But where is the family physician? In many cases he just isn't.

If the increasing demand of the American people for better distributed medical service finally produces socialized medicine, it will be because the profession has as yet made insufficient provision in its training program for the unceasing production of good family physicians. It is perfectly true that no one man can learn everything a good general practitioner needs to know. But some of our great teaching centers have stopped trying to tackle the problem. They have insidiously allowed their faculties to be monopolized by full-time research specialists who belittle the LMD. The entire atmosphere of the great schools and hospitals covertly points up the errors and inadequacies of the general practitioner, even though it has been a family doctor who diagnosed the need for consultation in nearly every hospital case the students see. Little do they realize how many of them later will themselves be the LMD. What is needed is a department of general practice in the medical schools, taught by suburban practitioners who bring the community viewpoint into

the classroom. For such teaching no large-city physician is qualified. The problem of medical care in the smaller community is outside the comprehension of the institutionalized specialist. The whole problem of prodromal symptoms and the early, uncertain pictures of the prediagnostic stages of common diseases is badly taught in large hospitals. The common maintenance therapeutic procedures of office or industrial practice are likewise poorly presented in the usual medical curriculum. Matters of social service, public-health facilities and liaison with charities and state or county facilities are ignored. And such viewpoints as the doctor's position and responsibilities as a citizen in the community are left untouched. These should be integral parts of the general practitioner's training. All physicians, of whatever specialty, should be familiar with them. A course in general practice should be required of all medical students, if only to emphasize the type of liaison necessary between family doctor and specialist. Specialists need to learn how often their care of the patient fails because of the lack of any instructions for follow-up study addressed either to the family physician or to the patient. Both groups need to know the vast difference in facilities between city office and country office and between home and hospital.

If socialized medicine comes, it will be partly at least because this job has not been done. When will the medical centers learn, as the medical societies are learning, that the backbone of American medicine is not in medical schools and hospitals but rather in communities, homes and offices all over the land? The real ambassador of American medicine to the people is not the public-relations expert of the large hospital, but rather the family doctor in thousands of villages and cities. And this the professors must learn if the profession is to maintain its place in the American system.

HENRY F. HOWE, M.D.

Cohasset, Massachusetts

BOOK REVIEWS

Medical Writing: The Technique and the Art. Morris Fishbein, M.D. With the assistance of Jewel F. Whelan. Second edition. 8°, cloth, 292 pp., with 36 illustrations. Philadelphia: The Blakiston Company, 1948. \$4.00.

The first edition of this small book was published in 1938. In this new edition an extensive revision has been based upon the handling of thousands of manuscripts for the *Journal of the American Medical Association* and the special periodicals of the Association. A very valuable chapter comprises the standard abbreviations for periodicals and serials listed, as well as an additional list of periodicals not now listed, in the *Quarterly Cumulative Index Medicus*. These lists are invaluable to medical librarians and all persons interested in the writing of medical papers. The list of recognized forms for eponymic diseases is likewise very important. It is taken from the standard nomenclature of the Association. The material is well arranged and covers the whole field of medical writing from the selection of the topic to the finished printed product. The publishing is excellent in every way. The volume should be in all medical libraries and should be accessible to all persons writing medical papers.

Germicides, Antiseptics and Disinfectants for Hospital Use. By Dewey H. Palmer. Paper. 15 pp. New York: Hospital Bureau of Standards and Supplies, Incorporated, 1948. \$1.00.

The service a patient receives in a hospital is the result of collaboration of many individuals. Such collaboration is easiest when there is a recognized hospital practice to serve as a basis for performance. This recent publication delineates the basis for choosing germicides, antiseptics and disinfectants and outlines techniques for their use. The contribution is noteworthy in that it represents the first attempt to provide an authoritative consensus on the relative merits of chemical disinfectants and special recommendations for hospital practice in this controversial field. In accomplishing this purpose, it inevitably focuses attention on the need for continuing investigation of the broad problem of detergents and germicides.

trations and 7 color plates St. Louis C V Mosby Company, 1948 \$5.50

This synopsis was written principally for medical students. The text covers briefly the whole field of ophthalmology. The printing is well done with a large type, and the illustrations and color plates are excellent. A good index completes the volume. The manual should prove useful to its intended clientele.

Arterial Hypertension. By David Ayman, M.D., instructor in medicine, Tufts College Medical School, associate visiting physician and head of out-patient clinic in hypertension, Beth Israel Hospital, Boston. Reprinted from *Oxford Loose-Leaf Medicine* with the same pagination. 8°, cloth, pp 508 (173-265) with 9 charts. New York: Oxford University Press, 1948. \$2.50.

This monogram on arterial hypertension, written by a specialist on the subject, emphasizes methods of treatment. A bibliography of ninety-nine references concludes the text. The volume is well published and should prove valuable to physicians interested in the subject.

NOTICES

ANNOUNCEMENT

Dr B. W. Mandelstam has left his position as assistant director at the Beth Israel Hospital, Boston, to assume that of executive director at the Nathan Littauer Hospital, Gloversville, New York.

NEW ENGLAND CENTER HOSPITAL (JOSEPH H. PRATT DIAGNOSTIC HOSPITAL)

30 Bennet Street, Boston
Lecture Hall, 9-10 a.m.

MEDICAL CONFERENCE PROGRAM

Friday, March 4 Mechanism of Blood Destruction in Congenital Hemolytic Jaundice. Drs. Charles P. Emerson, Jr., Shu Chu Shen, William B. Castle and Thomas Hale Ham (to be given by Dr. Ham).

Wednesday, March 9 Pediatric Clinicopathological Conference. Drs. James M. Baty and H. E. MacMahon.

Friday, March 11 Some New Methods for the Histochemical Demonstration of Enzymes and Compounds with Active Carbonyl Groups. Dr. Arnold N. Seligman.

Tuesday, March 15 Journal Review.

Friday, March 18 The Role of Mitochondria in Cellular Metabolism. Dr. William F. Loomis.

Tuesday, March 22 Surgical Emergencies in the New-Born. Dr. Lorye E. Hackworth.

Friday, March 25 Artificial Kidney. Dr. John M. Merrill.

From 9 to 10 a.m. on Wednesday (except the second Wednesday), Thursday and Saturday mornings clinics will be given by members of the hospital staff. Medical rounds are conducted each weekday except Saturday by members of the hospital staff from 12 to 1 p.m. On the second and fourth Fridays of the month, March 11 and 25 Therapeutic Conferences will be held with round-table discussion from 2 to 4 p.m., with Dr. Robert P. McCombs as moderator. On the second and fourth Fridays, March 11 and 25 Dr. Merrill Sosman will conduct X-Ray Conferences from 4 to 6 p.m.

All exercises are open to the medical profession.

GREATER BOSTON MEDICAL SOCIETY

A meeting of the Greater Boston Medical Society will be held in the auditorium, Boston University School of Medicine, 80 East Concord Street, Boston, on Wednesday, March 16, at 8:15 p.m. A symposium entitled "Vertigo and Simulative Symptoms" will be presented from the combined points of view of the anatomist, otologist, internist and neurosurgeon. The chairman will be Dr. Philip E. Meltzer, and the speakers

will be Dr. Miles Atkinson, of New York City, and Drs. Benjamin Spector and William H. Sweet.

NORFOLK DISTRICT MEDICAL SOCIETY

A meeting of the Norfolk District Medical Society will be held at the Boston Medical Library, 8 Fenway, Boston (Telephone Commonwealth 6-2800), on Tuesday, March 22, at 8 p.m.

The following scientific program, entitled "Symposium on Care of Advanced Cancer," will be presented:

Super-Radical Treatment. Ernest M. Daland, M.D.

Radiological Aspects. Joseph H. Marks, M.D.

Hormonal Aspects. Ira T. Nathanson, M.D.

Chemotherapeutic Aspects. Sidney Farber, M.D.

All physicians are invited.

NORFOLK DISTRICT WOMAN'S AUXILIARY

The Woman's Auxiliary of the Norfolk District Medical Society will meet in the State Suite at the Copley Plaza Hotel, Boston, on Tuesday, March 29, at 2:30 p.m. Mrs. Dorothy Hayward, R.N., assistant executive secretary, Health and Hospital Division, Greater Boston Community Council, will speak on the subject "Nursing in the Future."

NEW ENGLAND SOCIETY OF ANESTHESIOLOGISTS

The Committee on Education of the New England Society of Anesthesiologists plans to hold all-day, Saturday, clinics primarily for the physician practicing part-time anesthesia.

On Saturday, April 2, at the Rhode Island Hospital, Providence, Rhode Island, under the direction of Dr. Meyer Sallad. The morning session is devoted to clinical demonstrations and starts promptly at 8 o'clock. The afternoon session will be devoted to "Anoxia and Inhalation Therapy."

On Saturday, May 7, at the St. Francis Hospital, Hartford, Connecticut, under the direction of Dr. Stevens J. Martin. The morning session starts at 8 o'clock and is devoted to operative clinics; lectures will be held in the afternoon.

Any physician may attend by making reservations in writing to the respective directors. It is requested that reservations be made early.

PHI DELTA EPSILON LECTURE

The third annual Phi Delta Epsilon lecture, entitled "The Future Diabetic," will be delivered by Dr. Elliott P. Joslin at the Hahnemann Medical College, Philadelphia, on April 4.

All physicians, medical students and interested persons are invited.

WOMAN'S AUXILIARY, SUFFOLK DISTRICT

The Woman's Auxiliary of the Suffolk District Medical Society will hold its annual meeting and election of officers on Thursday, April 7, at 2:30 p.m. in Sprague Hall of the Boston Medical Library, 8 Fenway.

ASSOCIATION FOR PHYSICAL AND MENTAL REHABILITATION

The Association for Physical and Mental Rehabilitation will hold its third annual convention at the Hotel New Yorker, New York City, May 18-21. More than 500 representatives from the nation's Veterans Administration, Army, Navy and Civilian Rehabilitation Agencies will be present. Mr. Leo Berner, chief corrective therapist of the Bronx Veterans Hospital, is chairman for the convention.

Further information may be obtained from H. S. Wettstein, at the Corrective Therapy Section, Veterans Administration Hospital, Bronx, New York.

Failures in Psychiatric Treatment Edited by Paul H Hoch, M D, New York State Psychiatric Institute, New York City, principal research scientist (psychiatry), New York State Psychiatric Institute, and associate in psychiatry, Columbia University College of Physicians and Surgeons, New York City (The *Proceedings* of the thirty-seventh annual meeting of the American Psychopathological Association, held in New York City, June 1947) 8°, cloth, 241 pp, with illustrations New York Grune & Stratton, 1948 \$4.50

This symposium comprises the *Proceedings* of the annual meeting of the American Psychopathological Association, held in 1947, and contains fifteen papers read at the meeting. The text is concluded with a summary of the symposium findings by the editor. The book is well published, except that a coated paper has been used unnecessarily. The volume is recommended for all medical libraries.

Pathology of Tumours By R A Willis, D Sc, M D, F R C P, Sir William H Collins Professor of Human and Comparative Pathology, Royal College of Surgeons, London 8°, cloth, 992 pp, with 500 illustrations London Butterworth and Company (Publishers), Limited, 1948 \$20.00

Dr Willis has based his text largely on work done in the pathology laboratories of the Alfred Hospital, Melbourne, Australia, between the years 1930 and 1945. The volume is a personal treatise using the author's own observations and conclusions as fully as possible. Similarly, the illustrations, with a few exceptions of photomicrographs, are from personally studied material, and most of the illustrations have not previously been published. The depiction of well known appearances of common tumors has been omitted intentionally, and the less familiar and special features and the range of structure possible in the less common kinds of tumors have been shown, illustrations have not been repeated under different organs or structures. The text is divided into two parts. The first discusses classification and pathology in general. The second is devoted to descriptions of special tumors classified by organ or structure, followed by the tumors of general distribution, teratomas and chorionepitheliomas. Lists of selected references are appended to the various chapters. A comprehensive index concludes the volume. The type, printing and illustrations are excellent. The book was printed and bound in Great Britain and has an added American imprint. The treatise was written primarily for pathologists, research workers and senior medical students. It should be in all medical libraries and should be of interest to pathologists.

Vascular Diseases in Clinical Practice By Irving Wright, M D, associate professor of clinical medicine, Cornell University Medical College, and chief, Section on Vascular Diseases, Department of Medicine, New York Hospital 8°, cloth, 514 pp, with 104 illustrations Chicago The Year Book Publishers, Incorporated, 1948 \$7.50

This volume is one of the *General Practice Manuals* intended for the general practitioner. The first and second chapters discuss classification and methods of study of the patient. The following chapters are devoted to the different diseases of the vascular system. There is a chapter on industrial and medicolegal medicine in relation to peripheral vascular disease and injury, and an appendix on a method for determining plasma prothrombin. The material is well organized, and the text well written. Lists of pertinent references are appended to the chapters. The type and printing are good, but the coated paper is too heavy for the size of the volume. The manual should prove useful to the practicing physician.

Hutchison's Food and the Principles of Dietetics Revised by V H Mottram, M A (Cant.), and George Graham, M D (Cant.), F R C P (Lond), consulting physician to St. Bartholomew's Hospital 8°, cloth, 727 pp, with 28 illustrations Tenth edition Baltimore Williams and Wilkins Company, 1948 \$6.25

This standard treatise has been thoroughly revised. Much of the text has been rewritten, especially the first part, on

diet in normal life, which is practically new. The text is printed on a light paper with good type. There is a good index. The printing was done in Great Britain. The volume should be in all medical libraries.

Gynaecological and Obstetrical Anatomy By C F V Stout, M D, M R C S, assistant professor, Department of Anatomy, and sub-dean and tutor, Faculty of Medicine, University of Birmingham. With chapters on the histology of the female reproductive tract and its endocrine control, by F Jacoby, M D, Ph D, lecturer in history, department of anatomy, University College, Cardiff 8°, cloth, 248 pp, with 185 illustrations Baltimore Williams and Wilkins Company, 1948 \$11.00

The first edition of this book was published under the title of *The Anatomy of the Female Pelvis*. In this new edition the title has been changed to cover the new subject matter on the placenta and the anatomy of the fetus in its relation to childbirth. Large parts of the text have been entirely rewritten, and much material and many illustrations have been added. The various types of pelvis have been classified and described. Lists of selected references are appended to the chapters. There is a good index. The type and printing are good, and the color plates are excellent. The printing was done in Great Britain. The price is high for the size of the volume, although the color work must have been expensive. The work should be available to gynecologists and obstetricians. It should be in large medical libraries.

Handbook of Practical Bacteriology. A guide to bacteriological laboratory work By T J Mackie, C B E, M D, LL D, D P H, professor of bacteriology, University of Edinburgh, and director of bacteriological services, City of Edinburgh, and J E McCartney, M D, D Sc, director of research and pathological services, London County Council 8°, cloth, 624 pp Eighth edition Baltimore Williams and Wilkins Company, 1948 \$7.00

This standard English handbook of bacteriology has been completely revised and brought up to date. The data formerly published as an appendix to the war editions have been incorporated in the appropriate chapters. The material is well organized, and the text is well written. The publishing is excellent. The volume should prove useful as a guide to its subject.

Essentials of Public Health By William P Shepard, M D, M A. With the collaboration of Charles E Smith, M D, D P H, Rodney R Beard, M D, M P H, and Leon B Reynolds, Sc D. With a foreword by Ray L Wilbur, M D, LL D and Sc D, chancellor, Stanford University 12°, cloth, 600 pp, with 29 charts Philadelphia J B Lippincott Company, 1948 \$5.00

This volume constitutes a condensed handbook for the physician and medical student and other persons interested in public health. The subjects of tropical diseases and the public-health aspects of medical care are omitted from the manual. The text is based on the experience of the authors in teaching together for many years. A list of selected references is appended to each chapter. The volume is well published and should prove useful as a compendium on the subject.

Twentieth Century Speech and Voice Correction Edited by Emil Froeschels, M D, president, International Society for Logopedics and Phoniatrics, and president, New York Society of Speech and Voice Therapy 8°, cloth, 321 pp New York Philosophical Library, 1948 \$6.00

This work is the joint effort of nineteen specialists in various fields. The text reflects the latest developments in the subject of speech and voice correction. To each chapter is appended a selected list of references. The text is well printed with a good type on a soft nonglare paper. The volume is recommended as a reference source to all interested persons.

Handbook of Ophthalmology By Everett L Goar, M D, professor of ophthalmology, Baylor University College of Medicine, Houston, Texas 8°, cloth, 166 pp, with 45 illus

PROTHROMBIN A CRITIQUE OF METHODS FOR ITS DETERMINATION AND THEIR CLINICAL SIGNIFICANCE*

BENJAMIN ALEXANDER, M.D.,† ANDRE DE VRIES, M.D.,‡ AND ROBERT GOLDSTEIN, M.D.§

BOSTON

AS A result of the widespread use of dicumarol in the prevention and treatment of thromboembolism, clinicians have become increasingly interested in the role of prothrombin in blood coagulation. Investigators are aware that present technics for prothrombin estimation have their limitations. Failure to recognize them may prevent accurate diagnosis, obstruct effective therapy or even invite disaster. It is the purpose of this paper to delineate these limitations and to scrutinize current analytical procedures in the light of recent advances in knowledge of blood coagulation.

GENERAL CONSIDERATIONS

By chemical isolation and purification Seegers et al.¹ have defined the plasma protein component that is convertible to thrombin—namely, prothrombin. Until some other distinguishing physiological or biochemical property is found, determination of prothrombin must involve its conversion to thrombin, which is assayed by its ability to clot fibrinogen.

Recently, plasma factors have been reported that affect the conversion of prothrombin to thrombin by thromboplastin plus calcium.²⁻⁶ Just how they act is not clear, but it is probable that they accelerate, activate or otherwise act as ancillary agents in thrombin evolution. In any event their relation to the conversion of prothrombin to thrombin must be considered in the determination of prothrombin.

At present, no method of measuring prothrombin can assure adequate control of the nonprothrombin variables. Under such circumstances prothrombin values obtained by the generally accepted procedures are the result of several interrelated factors, of which only one is prothrombin. Accordingly, such

values express only "prothrombic activity"† instead of "amounts of prothrombin."

Most of the current analytical technics are based upon two methods: the one-stage procedure of Quick⁷ and the two-stage method of Warner et al.^{8||} In Quick's method the clotting time of the plasma is measured after optimal amounts of thromboplastin and calcium are provided. This, the prothrombin time, is the minimal interval that elapses before a macroscopic clot results from the conversion of prothrombin to thrombin. It reflects the amount of thrombin evolved together with the velocity of its evolution. The validity of the method rests upon the assumption that the velocity of prothrombin conversion to thrombin, as well as the latter's coagulation of fibrinogen, is a measure *solely* of prothrombin concentration.

In the two-stage procedure, prothrombin is presumably converted completely to thrombin in defibrinated and diluted plasma. By trial and error a suitable dilution is made that will yield a given amount of thrombin, as measured by its ability to clot a standard fibrinogen solution. Theoretically, sufficient time is allowed to complete prothrombin conversion, obviating possible variations in the velocity of this reaction. Prothrombin is thus measured by the amount, not by the velocity, of thrombin formation.

Frequently, the results obtained by both methods agree closely. Sometimes, however, there is considerable (as much as 100 per cent) discordance between the results—for example, in different species, in infants and in aged plasma, dicumarolized blood and hemophilic serum. Until these discrepancies are satisfactorily explained, results obtained by either method must be interpreted cautiously.

ONE-STAGE METHOD

General Procedure

Oxalated plasma is added to potent thromboplastin extract, the mixture is brought to 37°C,

*We consider this term necessary to distinguish between the amount of prothrombin and such and the activity of a given biologic mixture in the production of thrombin for converting fibrinogen to fibrin.

||We have not included the method of Shonheyder⁹ which is based upon the inverse relation between prothrombin concentration and the amount of thromboplastin required to clot plasma in one hundred and eighty seconds.

*From the Medical Research Laboratory, Beth Israel Hospital and the Department of Medicine, Harvard Medical School. Supported by a grant from the Commonwealth Fund.

†Associate in medicine, Harvard Medical School; visiting physician and associate in medical research, Beth Israel Hospital.

‡Research fellow in medicine, Beth Israel Hospital; formerly fellow, the Rothschild Hadassah University Hospital, Jerusalem, Palestine.

§Assistant in medicine, Harvard Medical School; associate in medicine, Beth Israel Hospital.

MASSACHUSETTS PHYSICIANS ART ASSOCIATION

The Massachusetts Physicians Art Association will hold its annual exhibit in conjunction with the annual meeting of the Massachusetts Medical Society at Worcester, May 24-26. This exhibit includes oil and water-color paintings, drawings, etchings, photographs, carving, sculpture and any other original decorative handiwork done by members. Any member of the Massachusetts Medical Society is eligible for membership and may exhibit this year on payment of \$2.00 annual dues to Dr. Robert Buck, 5 Bay State Road, Boston, treasurer. Nothing will be accepted for the exhibit after May 1. Members will receive further details concerning final arrangements later.

REGULAR CORPS EXAMINATION FOR MEDICAL OFFICERS IN UNITED STATES PUBLIC HEALTH SERVICE

A competitive examination for appointment of medical officers in the Regular Corps of the United States Public Health Service will be held on May 3, 4, and 5, 1949. Appointments, which will be made in the grades of assistant surgeon (first lieutenant) and senior assistant surgeon (captain), are permanent and provide opportunities to qualified physicians for a lifetime career in clinical medicine, research and public health.

As requirements for appointment in the grade of assistant surgeon, the applicant must be a citizen of the United States, at least twenty-one years of age and a graduate of a recognized school of medicine. Physicians now serving internships, who are successful on the examination, will not be placed on active duty in the Regular Corps until completion of internship. Applicants for appointment in the grade of senior assistant surgeon, in addition to the above requirements, must have a total of at least ten years of educational training and professional experience subsequent to high school. (All commissioned officers are appointed to the general service and are subject to change of station.) Qualifying applicants will receive written professional tests, an oral interview, and a physical examination.

Application forms and additional information may be obtained from Surgeon General, United States Public Health Service, Washington 25, D. C. (Attention: Division of Commissioned Officers). Complete applications must be received by April 4, 1949.

PROTHROMBIN: A CRITIQUE OF METHODS FOR ITS DETERMINATION AND THEIR CLINICAL SIGNIFICANCE*

BENJAMIN ALEXANDER, M.D.,† ANDRE DE VRIES, M.D.,‡ AND ROBERT GOLDSTEIN, M.D.§

BOSTON

AS a result of the widespread use of dicumarol in the prevention and treatment of thrombosis, clinicians have become increasingly interested in the role of prothrombin in blood coagulation. Investigators are aware that present techniques of prothrombin estimation have their limitations and that failure to recognize them may prevent accurate diagnosis, obstruct effective therapy or even invite disaster. It is the purpose of this paper to delineate these limitations and to scrutinize current analytical procedures in the light of recent advances in knowledge of blood coagulation.

GENERAL CONSIDERATIONS

By chemical isolation and purification Seegers and his associates¹ have defined the plasma protein component that is convertible to thrombin—namely, prothrombin. Until some other distinguishing physiological or biochemical property is found, determination of prothrombin must involve its conversion to thrombin, which is assayed by its ability to clot fibrinogen.

Recently, plasma factors have been reported that affect the conversion of prothrombin to thrombin in the presence of thromboplastin plus calcium.²⁻⁶ Just how they act is not clear, but it is probable that they accelerate, activate or otherwise act as ancillary agents in thrombin evolution. In any event, their action on the conversion of prothrombin to thrombin must be considered in the determination of prothrombin.

At present, no method of measuring prothrombin can assure adequate control of the nonprothrombin variables. Under such circumstances, prothrombin values obtained by the generally accepted procedures are the result of several interrelated factors, of which only one is prothrombin. Accordingly, such

values express only "prothrombic activity"⁶ instead of "amounts of prothrombin."

Most of the current analytical techniques are based upon two methods: the one-stage procedure of Quick⁷ and the two-stage method of Warner et al.⁸ In Quick's method the clotting time of the plasma is measured after optimal amounts of thromboplastin and calcium are provided. This, the prothrombin time, is the minimal interval that elapses before a macroscopic clot results from the conversion of prothrombin to thrombin. It reflects the amount of thrombin evolved together with the velocity of its evolution. The validity of the method rests upon the assumption that the velocity of prothrombin conversion to thrombin, as well as the latter's coagulation of fibrinogen, is a measure solely of prothrombin concentration.

In the two-stage procedure, prothrombin is presumably converted completely to thrombin in defibrinated and diluted plasma. By trial and error a suitable dilution is made that will yield a given amount of thrombin, as measured by its ability to clot a standard fibrinogen solution. Theoretically, sufficient time is allowed to complete prothrombin conversion, obviating possible variations in the velocity of this reaction. Prothrombin is thus measured by the amount, not by the velocity of thrombin formation.

Frequently, the results obtained by both methods agree closely. Sometimes, however, there is considerable (as much as 100 per cent) discordance between the results—for example, in different species, in infants and in aged plasma, dicumarolized blood and hemophilic serum. Until these discrepancies are satisfactorily explained, results obtained by either method must be interpreted cautiously.

ONE-STAGE METHOD

General Procedure

Oxalated plasma is added to potent thromboplastin extract; the mixture is brought to 37°C,

*We consider this term necessary to distinguish between the amount of prothrombin as such and the activity of a given biologic mixture in the production of thrombin for converting fibrinogen to fibrin.

†We have not included the method of Shonheyder,⁹ which is based upon the inverse relation between prothrombin concentration and the amount of thrombin required to clot plasma in one hundred and eighty seconds.

and calcium chloride solution added. From this instant the time required for clotting (the prothrombin time) is measured.

Serum prothrombin is similarly determined except that fibrinogen must also be provided.

Certain Clotting Components

Fibrinogen. The clinical and experimental value of the one-stage method needs no elaboration. Nevertheless, it suffers from several limitations. For example, afibrinogenemic blood containing normal amounts of prothrombin will show an infinitely prolonged prothrombin time, which would be interpreted as indicating zero prothrombin. The addition of fibrinogen rectifies this defect. The relation between fibrinogen concentration and prothrombic

The reactivity of fibrinogen to thrombin differs also from one species to another.¹⁴ This must be duly considered when apparent prothrombin concentration of one species is compared with that of another.

Labile factor. As plasma ages its prothrombin time increases, and yet its prothrombin concentration, as determined by the two-stage technic or by chemical isolation, may be normal.¹⁵ The decrease in prothrombic activity is due to deterioration of a labile component found in fresh plasma,* which is necessary for the rapid conversion of prothrombin to thrombin.² This factor, more labile at refrigerator or body temperature than prothrombin, is not fibrinogen, and is not appreciably adsorbed by barium sulfate, in contradistinction to prothrombin.¹¹

No case of deficiency of labile factor has been recorded. Two subjects in whom the elevated prothrombin time seemed due, at least in part, to low concentrations of labile factor were observed. The plasma of Subject 1, who had extensive hepatic damage from obstructive jaundice with a malignant tumor involving the liver, showed much less prothrombic activity by the orthodox one-stage technic than when the determination was made on a mixture of his plasma with normal plasma rendered prothrombin free by adsorption with barium sulfate (Table 2), as pointed out below. Furthermore, the

activity is shown in Table 1. Since hypofibrinogenemic plasma may exhibit decreased prothrombic activity despite normal prothrombin content, an elevated prothrombin time must be interpreted cautiously in those conditions in which fibrinopenia as well as hypoprothrombinemia may occur (such as liver disease).

The quality of fibrinogen and the milieu in which it is dissolved are also important. We have observed that as plasma ages, it clots less readily on the addition of thrombin. Whether this is referable to alteration in the fibrinogen or to changes in other plasma components¹⁰ is still unknown. In either case such changes, spontaneously occurring or artificially induced, can conceivably affect the prothrombin time. The decreased prothrombic activity of plasma stored for as much as four weeks is not necessarily due to changes in fibrinogen, however, since deprothrombinated, fibrinogen-free plasma can restore prothrombic activity to such plasma.¹¹⁻¹³

patient's plasma was far less able to rectify the prolonged prothrombin time of stored plasma than normal plasma was. The plasma of Subject 2, with chronic myelogenous leukemia, behaved similarly (Table 3). Clearly, these subjects lacked a component (not prothrombin) present in fresh normal plasma that is necessary for normal prothrombic activity in the one-stage method and is deficient in stored plasma.

*It is for this reason that the plasma must be fresh for the accurate determination of plasma prothrombin by the orthodox one stage procedure.

It is probable that many similar observations will be made when more practical methods of measuring the labile factor, such as that of Stefanini and Quick,¹⁶ are widely applied. Prothrombic activity is distinctly decreased¹¹ when the concentration of this factor is less than 50 per cent of normal. Furthermore, the effect of suboptimal concentration of labile factor is more pronounced if the prothrombin is also below normal. Accordingly, an elevated prothrombin time of a given plasma sample may be due to deficiencies of prothrombin, labile factor or fibrinogen singly or in combination.

Other Plasma Components That Accelerate the Conversion of Prothrombin to Thrombin

To these variables must be added the accelerator globulin of Seegers,⁴ Factor V of Owren,³ prothrombin A of Quick² and plasma factor of Fantl and Nance.⁵ Apparently, these entities also accelerate the conversion of prothrombin to thrombin. Hemorrhagic episodes and hypoprothrombinemic activity due to deficiency of Factor VI¹⁷ and prothrombin A² have been established. Furthermore, after acute liver poisoning by chloroform in dogs, not only prothrombin but also plasma accelerator globulin falls, contributing to the low plasma prothrombic activity.¹³ Here, too, the elevated prothrombin time, signifying a relatively retarded evolution of thrombin from prothrombin, reflected inadequacies in accelerator globulin as well as prothrombin.

Antithrombin In both the one-stage and two-stage techniques the thrombin evolved from prothrombin is assayed by its ability to convert fibrinogen to fibrin. Validity of this measurement depends upon the presupposition that no agent is present that will inactivate the evolved thrombin or otherwise interfere with its clotting of fibrinogen. This supposition is incorrect since plasma contains antithrombin, which can inactivate appreciable quantities of thrombin. The longer the thrombin is in contact with antithrombin, the greater the amount inactivated. Furthermore, heparin enhances this inactivation.¹⁹ Unfortunately, little is known regarding the plasma concentration of antithrombin or heparin, or both, under pathologic conditions. Conceivably, variations in plasma antithrombin or in circulating heparin or heparin-like anticoagulants, as in certain hemorrhagic disorders,²⁰⁻²¹ can influence prothrombic activity considerably. This would be especially true in hypoprothrombinemia in which the amount of thrombin evolved was so small or its evolution so slow that antithrombin activity could play a substantial role. To what extent plasma antithrombic activity may influence prothrombin time awaits further investigation.

Other clotting inhibitors Other circulating anticoagulants have recently been described²²⁻²³ that affect the rate of thrombin evolution from prothrombin. They may similarly affect prothrombin

determinations by the one-stage procedure. Considerable work is necessary to explore this possibility.

Serum prothrombic activity Some of the foregoing considerations bear particularly on the determination of serum prothrombin. Obviously, the absence of fibrinogen must be rectified. Furthermore, little is known concerning the concentration in serum of other important clotting constituents. We have found that under certain conditions labile factor may be considerably reduced, or may indeed disappear, during coagulation.²⁴

Coagulation is also attended by the appearance of substances that accelerate or activate the con-

version of prothrombin to thrombin by thromboplastin and calcium.²⁵⁻²⁸ A mixture of plasma with serum devoid of prothrombin shows greater prothrombic activity than can be attributed to the plasma prothrombin in the mixture.²⁴⁻²⁶ The amount of the accelerator in serum is related to the amount of prothrombin consumed in the process of coagulation, and varies under pathologic conditions.²⁷⁻²⁸ Obviously, elaboration of this substance during clotting may affect appreciably the apparent prothrombic activity of serums. We have observed, for example, that after the coagulation of hemophilic blood, the serum often exhibits from 50 to 100 (or more) per cent of the original plasma prothrombic activity when measured by the one-stage procedure.²⁸ By the two-stage technic, however, far less serum prothrombin is demonstrable. Accordingly, determination of serum prothrombin concentration from serum prothrombin time may be erroneous. Furthermore, computations of the prothrombin consumed during coagulation from differences between plasma and serum prothrombic activities must be viewed with caution.

In view of the prothrombin-enhancing effect of serum every precaution should be taken in draw-

ing blood for prothrombin determination against partial coagulation, which may occur when venipuncture is not immediately successful and when the blood does not flow freely into the syringe

Weaknesses and Limitations Related to Thromboplastin Reagent

In determining prothrombin its conversion to thrombin by thromboplastin should not be limited by the quantity or quality of this clotting agent. Nevertheless, the source of thromboplastin and the method of its preparation profoundly affect the prothrombin time although it is presumably provided

This "normal control value" may not be representative of the average normal subject since marked variations in prothrombic activity may occur from person to person or in the same person from day to day. A given prothrombin time can be interpreted, therefore, only in the light of the range of values obtained with the same thromboplastin on a group of normal subjects.

It has also been reported that a given thromboplastin extract may show low potency when tested on whole plasma but good activity when tested on diluted plasma.^{30, 31} Similarly, under certain conditions diluted thromboplastin is more potent

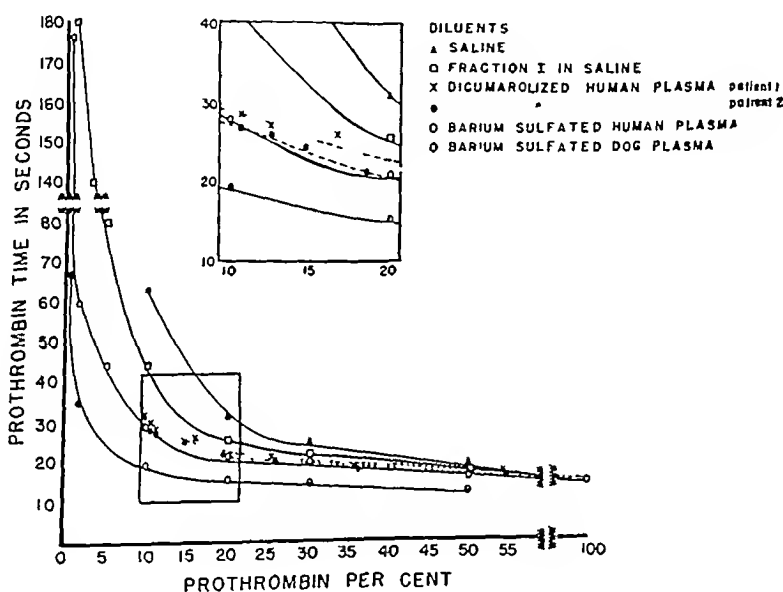

FIGURE 1 Relation between Prothrombin Time and Prothrombic Activity of Normal Human Plasma Diluted with Various Diluents

Fraction I in saline solution contained 500 mg of Harvard Fraction I per 100 cc. Patients 1 and 2 were subjects with myocardial infarction treated with dicumarol. Their plasmas, used as diluents, contained, respectively, 7.6 and 9.4 per cent (of normal) prothrombic activity. These figures were used in computing the prothrombin percentage in the dicumarolized plasma and normal plasma mixtures.

in excess. Quick²⁹ uses only fresh rabbit-brain extract, which for normal plasma gives a prothrombin time of 11.0 to 12.5 seconds. For practical reasons most clinical laboratories employ commercial thromboplastin preparations, which rarely give such a low prothrombin time and which vary considerably in potency from batch to batch even from the same manufacturer.* Furthermore, thromboplastin extracts deteriorate fairly rapidly in the liquid state. In view of these variations the prothrombin time of a given plasma sample has little significance unless it is accompanied by a value obtained with the same thromboplastin on a normal subject.

*This may be due to the presence of anticoagulants in thromboplastin extracts from brain.³²

than concentrated thromboplastin.³¹ Profound differences in prothrombin time are also obtained even on the same plasma when Russell-viper venom is used instead of brain extract.^{31, 32} From the foregoing, it is evident how considerable confusion regarding prothrombin concentration and prothrombic activity may arise owing to the use of different thromboplastin preparations.

Relation between Prothrombic Activity and Prothrombin Time

Fundamental to the one-stage method is the curve relating prothrombin time with prothrombic activity (Fig 1). From such curves the observed prothrombin time is translated into prothrombic ac-

tivity In the range of 25 to 100+ per cent (of normal) prothrombic activity a substantial reduction results in a very small increment in prothrombin time Therefore, conversion of a given prothrombin time into prothrombic activity is in this range only an approximation This has been strongly emphasized by Link.³³ Attempts have been made^{34, 35} to circumvent the difficulty by prior dilution of the test plasma to a range where a relatively small alteration in activity is reflected by a large change in prothrombin time In this way hypoprothrombinemia can be detected long before it becomes apparent from determinations on undiluted plasma

Dilution technic The diluent employed for this purpose is extremely important Ideally, it should be plasma that is devoid of prothrombin but normal in all other clotting components Dilution with saline solution, a procedure widely used,³⁵ is unsatisfactory because it dilutes other clotting factors as well as prothrombin Subnormal levels of these substances may thus become exaggerated, consequently affecting the prothrombic activity considerably The addition of fibrinogen to the diluent³⁶ assures adequacy of only one component When a saline solution of fibrinogen is used as diluent, the curve relating prothrombic activity with prothrombin time differs considerably from that derived with saline solution alone (Fig 1) Different curves are furthermore obtained when plasma is diluted with plasma that has been rendered prothrombin free by prior adsorption with barium sulfate (Fig 1) This agent removes prothrombin almost quantitatively as well as a small amount of nonprothrombin protein.³⁷ The question arises whether the additional material adsorbed consists of nonprothrombin clotting factors As far as we know, the smallest amount of barium sulfate required to adsorb the prothrombin does not remove other important plasma clotting constituents.*

Dicumarol decreases plasma prothrombin, presumably by inhibiting its production in the liver.³⁸ Most investigators agree that other clotting factors are not affected to any considerable degree Plasma from a dicumarolized subject whose prothrombin has been markedly reduced should, therefore, be an ideal diluent in the determination of prothrombic activity of any unknown plasma The curves relating prothrombic activity with prothrombin concentration are practically identical when either dicumarolized or barium sulfate plasma is used as diluent (Fig 1) Furthermore, adsorbing dicumarolized plasma with barium sulfate does not alter the relation (Fig 2) This indicates that the adsorbing agent does not remove important clotting factors present in the dicumarolized plasma From the point of view of ready availability, barium sulfate

plasma is preferable to dicumarolized plasma as a diluting agent †

By the one-stage technic dog plasma shows greater prothrombic activity than human plasma.³⁹ By the two-stage procedure, however, the activities are essentially the same in both species.⁴⁰ Since there is no evidence that dog prothrombin differs in its reactivity from human prothrombin, the discrepancy is most likely referable, at least in part, to nonprothrombin factors In support of this interpretation is the fact that human plasma diluted with barium sulfate *prothrombin-free dog* plasma exhibits much greater prothrombic activity than that diluted with barium sulfate *prothrombin-free human* plasma (Fig 1) Similar results are obtained with

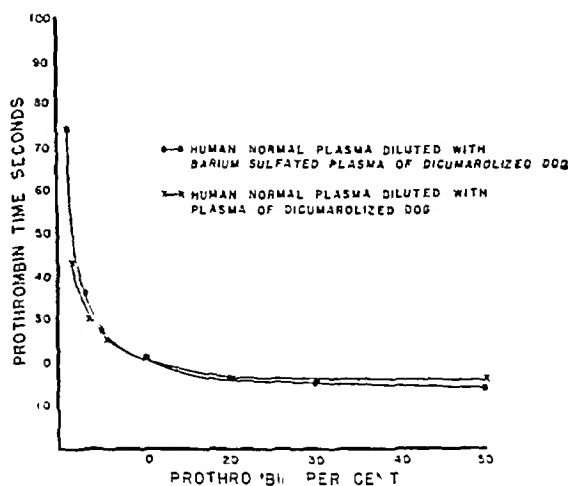

FIGURE 2 Comparative Effects of Dicumarol and Barium Sulfate on Plasma in Relation to Its Use as Diluent in the Determination of Prothrombin

The dog received a total of 187 mg of dicumarol per kilogram of body weight intramuscularly for twelve days before the experiment The prothrombic activity of the plasma, which was used as diluent, was 0.5 per cent

prothrombin-free rabbit plasma It is not clear whether this is due to the presence in these species of an as yet unknown factor not present in man or to larger amounts of known nonprothrombin clotting factors that influence prothrombic activity.‡ If the latter were true, barium sulfate dog or rabbit plasma might be preferable as a diluent in the one-stage procedure, since excesses of these factors might thus be assured

Some investigators have used plasmas rendered prothrombin free in other ways — namely, by ad-

*Barium sulfate is said to remove approximately 50 per cent of Factor V from plasma but how much is required to do this is not reported.³

†It should be mentioned that recent evidence suggests that dicumarol affects the clotting system of plasma in more ways than mere reduction in prothrombin.⁴¹ If this is so it is noteworthy that barium sulfate has the same effect.

‡Omick and Stefannini⁴² have found that more labile factor is present in dog plasma than in human plasma.

sorption with aluminum hydroxide,^{6, 41} with tricalcium phosphate¹⁷ or by passage through Seitz filters.³ Before these procedures can be evaluated one should know whether or not they also affect the nonprothrombin-clotting components.

The preparation of barium sulfate plasma requires complete separation of the adsorbing agent since residual traces may affect, by continued adsorption, the prothrombin of the test plasma that is diluted.⁴² This probably holds true also when other adsorbing agents are used.

It should be remembered, furthermore, that the labile factor is at least just as labile in prothrombin-free as in whole plasma. Accordingly, the deprothrombinated plasma should be used shortly after preparation. We have found barium sulfate plasma fully potent for at least five hours if it is kept refrigerated.

Other Important Variations in the One-Stage Procedure

The prothrombin time is considerably influenced by the order with which the reagents are mixed. In most laboratories thromboplastin and calcium are added to plasma. In others, however, the order is reversed.⁴³

It should be pointed out also that 0.02M calcium chloride, the concentration generally used in the prothrombin determination, has recently been found inadequate for dicumarolized plasma²⁹; 0.025M calcium chloride is recommended instead. In the light of this finding older studies of the effects of dicumarol will need re-evaluation.

TWO-STAGE METHOD

General Procedure

The two-stage technic is based upon *complete* conversion of prothrombin to thrombin by thromboplastin plus calcium. The yield of thrombin is subsequently measured. By definition, 1 unit of prothrombin gives 1 unit of thrombin, and 1 unit of thrombin is that amount which will clot 1 cc of a standard fibrinogen solution in fifteen seconds at 28°C.⁸

In the determination the test plasma is defibrinated by the addition of a small amount of thrombin, excesses of which are inactivated by incubation. The mixture is then diluted serially with saline solution, the dilutions are treated with thromboplastin and calcium, and the resultant mixtures allowed to stand until conversion of prothrombin to thrombin is complete. They are then reacted with a solution of fibrinogen. A sample of the dilution that induces coagulation in fifteen seconds is considered to contain 1 unit of thrombin. From the dilution the concentration of thrombin (in units), or its precursor, prothrombin, is computed.

Weaknesses and Limitations

Antithrombin Perhaps the most serious limitation of the two-stage procedure is in the determination of plasma prothrombin when its concentration is low. With relatively normal prothrombin levels the method calls for high dilution of the plasma. Hypoprothrombinemic plasma, however, must be diluted *less* than normal plasma to furnish a mixture that will yield sufficient thrombin to clot the standard fibrinogen solution in the required time. Because of this, thrombin inactivation by antithrombin may become formidable, leading to gross inaccuracies. The lower the prothrombin, the greater the question of antithrombin activity looms. For clinical purposes, where interest is focused largely on hypoprothrombin conditions, this drawback makes the procedure of limited value. A method to circumvent antithrombin activity has been reported,⁴⁴ but experience with it has been limited.

Importance of nonprothrombin factors affecting the evolution of thrombin In the two-stage procedure *complete* conversion of prothrombin and measurement of the evolved thrombin is assumed *before* the influence of antithrombin supervenes. As mentioned above, Ware and Seegers⁴ have shown that prothrombin conversion is both retarded and incomplete when accelerator globulin is decreased or absent. This may occur under certain pathologic conditions in which hypoprothrombinemia has also been observed.¹⁸ The serious effect of antithrombin when thrombin evolution is slow has already been discussed. Seegers et al.^{18, 45} have accordingly modified the two-stage method by providing supplements of accelerator globulin.

Other factors have recently been described (Factor V of Owren⁸ and labile factor²), which similarly accelerate the conversion of prothrombin to thrombin. The question arises whether they too should be provided to a test plasma to assure complete as well as rapid prothrombin conversion. Since none of them are available commercially, they would have to be prepared independently—a laborious task. Otherwise, deprothrombinated plasma must be added to the prothrombin-thromboplastin-calcium reaction mixture, a procedure not unlike the dilution technic of the one-stage method. This would introduce the untoward effects of antithrombin.

Serum prothrombin These considerations bear significantly on the two-stage determination of serum prothrombin. As pointed out above, serum not only is devoid of fibrinogen but also frequently contains suboptimal amounts of labile factor.⁴⁴ Furthermore, accelerator globulin is relatively unstable in human serum.⁴⁵

Also to be considered is evidence indicating that thrombin is capable of destroying prothrombin.⁴⁶ It will be recalled that in the two-stage procedure the test plasma is first defibrinated by additions of

thrombin In serum, also, thrombin has been evolved as a consequence of coagulation To what extent this clotting agent, added or spontaneously elaborated, affects the prothrombin in question requires further elucidation

Laboriousness of the two-stage technic Practically all investigators agree that the two-stage technic is much more laborious than the one-stage procedure This precludes its routine use in most clinical laboratories

AIMS AND ORIENTATION OF THE PHYSICIAN

The physician who requests a prothrombin determination should have a clear idea of the information he seeks Does he want to know the precise concentration of this factor in contradistinction to other clotting constituents? Or does he seek an over-all appraisal of the ability of the plasma to evolve thrombin, which may help him detect a more general coagulation defect underlying a hemorrhagic disorder? And, above all, the physician prescribing dicumarol for the prevention or treatment of thromboembolic disease wants to know the effective, yet safe, "prothrombin level," whether his patient is within that range, and how he can be kept there consistently It should be emphasized that one who undertakes anticoagulant therapy tampers with one of the most important homeostatic functions of the body, and that dicumarol strikes at the keystone in the mosaic of the blood clotting mechanism

And how should the physician interpret the results reported by the laboratory? Considerable confusion exists in the minds of practitioners regarding the terms "prothrombin per cent," "prothrombin time," "normal control," "diluted prothrombin time," "prothrombin activity" and "clotting time" and their relations to each other

Confusion would be avoided if a sound and simple modification of the two-stage procedure were available since with this technic quantitation is in terms of clearly defined units For various reasons, some of them discussed above, this procedure is employed in very few clinical laboratories

At the risk of repetition the above terms are reconsidered "Prothrombin time" is an empiric interval representing the minimal time required for oxalated or citrated plasma to clot when provided with optimal amounts of thromboplastin and calcium Practically speaking, it bears no relation to the clotting time of whole blood, or to the clotting time of recalcified plasma (recalcification time) In normal subjects it may be between 12 and 14 or more seconds, depending upon individual variation in prothrombic activity and upon the thromboplastin preparation used in the determination

"Prothrombin concentration" refers to the actual level of prothrombin in the plasma, and is expressed in percentage ("prothrombin per cent") of what is

found in normal subjects* This must be distinguished from "prothrombin activity," or, as we propose, "prothrombic activity," which indicates the over-all ability of plasma to form thrombin in the presence of optimal thromboplastin and calcium, reflecting the activities not only of prothrombin but also of nonprothrombin clotting factors

Prothrombic activity, also expressed in percentage of normal, is calculated by interpolation of the observed prothrombin time on a standardization curve, that relates prothrombin time with various degrees of dilution of normal plasma Different curves are obtained with different diluents The advantage as diluent of prothrombin free, yet otherwise normal, plasma is that it assures normal amounts of nonprothrombin clotting factors, thus permitting determination of actual prothrombin concentration The prothrombin concentration of a test plasma can be computed from the prothrombin time observed on the plasma similarly diluted with the prothrombin free plasma As far as we can determine, barium sulfate plasma approaches the ideal diluent most closely

Lowering the concentration of prothrombin or various plasma clotting components results in little increase in the prothrombin time until prothrombic activity is about 25 per cent of that found in the average normal subject The difference in prothrombin time between plasma containing 50 per cent of normal prothrombic activity and 100+ per cent is practically within the limits of accuracy of the measurement Accordingly, reports of prothrombic activity (as determined on *whole* plasma) in this range have little significance except to indicate that the activity is above 50 per cent

Determinations on diluted plasma ("diluted prothrombin time") are more precise and are especially useful in the range of prothrombic activity exceeding 15 per cent of normal Below this, little is gained by this modification, since sufficient accuracy is obtained by determining the prothrombic activity on whole plasma If, however, information is desired concerning the concentration of prothrombin itself rather than of its activity in conjunction with nonprothrombin factors that also affect the prothrombin time, dilution with prothrombin free (yet otherwise normal) plasma offers distinct advantages

It is important to recognize the wide variation in the prothrombic activity of normal persons The "control value," obtained on one normal subject and reported side by side with the value given for a test plasma, serves merely to indicate the potency of the thromboplastin reagent used, and by no means as a basis for strict comparison

Experience indicates that when prothrombic activity exceeds 20 per cent of normal, hemorrhage is rarely, if ever, due to deficiency of prothrombin, its activators or fibrinogen This degree of hypo-

*In the two-stage technic prothrombin concentration is expressed in units. Normal human plasma is said to contain 300 units per cubic centimeter

prothrombic activity can be readily detected by measurements on undiluted plasma

Frequently it may be desirable to determine whether the clotting defect is due to low prothrombin per se or to inadequacy of the other factors belonging to the prothrombin constellation*. This can be done by simultaneous determinations with the nonprothrombin factors provided (by diluting with prothrombin-free normal plasma) and without providing these factors (by determining prothrombin on the undiluted plasma). If low activity is due to deficiency of prothrombin alone the results will agree

It has been repeatedly observed that the prothrombin time of dicumarolized subjects fluctuates sharply. Many of the reasons for this are clear. In a dog that receives a large dose of the drug about 80 per cent of the plasma prothrombin disappears within twenty-four hours (Fig 3). The remaining 20 per cent is still sufficient to give a relatively normal prothrombin time since the difference in prothrombin time between plasma with 100 per cent prothrombin and that with 20 per cent is only slight (Fig 1). During the next ten hours the prothrombin continues to decline precipitously and reaches suffi-

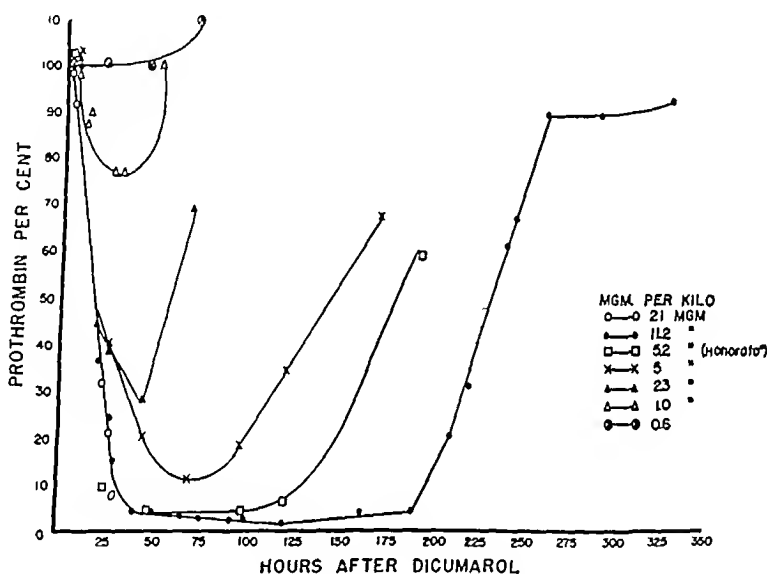

FIGURE 3 Effect of Varying Doses of Dicumarol on the Plasma Prothrombin Concentration in the Dog

All observations, with the exception of those of Honorato,¹² were obtained on the same animal. Dicumarol was administered intramuscularly as a suspension in propylene glycol.

closely. If, however, the low activity is referable to nonprothrombin factors, the value obtained by the dilution technic will be higher (after correction for dilution) than that obtained on undiluted plasma.

The estimation of prothrombic activity in the patient who is about to receive, or is receiving, dicumarol deserves special consideration. The drug apparently acts by blocking prothrombin synthesis in the liver. The goal of therapy is reduction of circulating prothrombin to a level where intravascular clotting is prevented or stopped, but not to the point where hemorrhage is likely to ensue. Obviously, a delicate balance must be attained between the velocity with which prothrombin disappears from the blood after its formation is blocked and the speed with which it is regenerated when the drug is eliminated.

ciently low levels to give markedly elevated prothrombin times.

If dicumarol had been given to an animal with a prothrombic activity of only 30 per cent or less (of normal), the drug would have induced an elevated prothrombin time within a much shorter interval. Since determinations by the orthodox technic could hardly have distinguished with certainty between 30 per cent prothrombin and 100 per cent, the quicker effect might have been attributed to undue sensitivity to the drug. This indicates the importance of knowing prothrombic activity precisely before dicumarol administration.

The regeneration of prothrombin when the effects of dicumarol are wearing off is equally rapid (Fig 3). An elevated prothrombin time can return very quickly to a relatively normal one without necessarily indicating restoration of 100 per cent of the

*For the purposes of this paper fibrinogen is included in this constellation.

prothrombic activity. If to these considerations are added differences in the weights of patients,* possible variations in rate of absorption† of the drug from the intestinal tract, and individual variations in liver function or other bodily functions controlling prothrombin synthesis and dicumarol elimination,‡ one can readily understand the wide and sharp fluctuations in plasma prothrombic activity often observed during dicumarol therapy.

The conclusion appears inescapable that the best guide to dicumarol therapy is frequent and precise determinations of prothrombic activity as well as prothrombin concentration. In the range of 15 to 100+ per cent of prothrombin (12-second to 16-second prothrombin time) precision can best be attained by the use of a proper dilution technic.

It is difficult to state what concentration of prothrombin is both "safe" and effective in prevention or treatment of thromboembolism. The literature is replete with recommendations that a prothrombin time of between 30 and 40 seconds, or that a level of 20 per cent of prothrombin, should be maintained. While experience indicates that a prothrombin time of 30 to 40 seconds is safe in persons with otherwise normal hemostatic function, it may be hazardous in the presence of other disturbances in the hemostatic mechanism. Furthermore, such a prothrombin time has little significance unless the potency of the thromboplastin used is known from prior standardization on normal subjects. Also, many of the reports recommending a prothrombin concentration of 20 per cent are based upon saline dilution curves. In the light of the advances made in the determination of prothrombin this figure is no longer tenable.

In our experience a prothrombin concentration of between 5 and 10 per cent of normal (obtained by the procedure outlined below) can usually be regarded as safe. Also, at this level coagulation is defective.²⁴ How effective this is against thrombotic disorders requires further clinical observation.

RECOMMENDED PROCEDURE FOR PROTHROMBIN DETERMINATION

The method that we consider at the present time most satisfactory for general clinical use in the determination of prothrombin is outlined in detail. The technic is essentially the one-stage method of Quick as modified by Rosenfield and Tuft.²⁷

Thromboplastin extract (prepared from Difco thromboplastin⁴⁶) is pipetted in 0.1-cc amounts into each of many prothrombin-time test tubes, which are then stored at -10°C until used. The extract thus stored in the frozen state in ready-to-use units retains its potency for as long as seven months.⁴⁶ To standardize it, prothrombin times on a plasma

pool from at least 5 normal subjects are determined with each batch according to the following technic.

Barium sulfate plasma§ To each cubic centimeter of fresh normal plasma is added 0.1 gm of powdered barium sulfate (C.P.). The mixture is shaken, placed in the incubator at 37°C for fifteen minutes, during which it is shaken frequently, and then centrifuged for thirty minutes at 3000 r.p.m., after which the supernatant is carefully separated. This barium sulfate plasma, used as the diluent, should be kept at refrigerator temperature ($4-5^{\circ}\text{C}$) and should be used within five hours of preparation.

Standardization curve Various dilutions are made of the pooled normal plasma with the barium sulfate plasma, 0.10 cc of each of the dilutions is added to a thromboplastin tube that has been thawed for ten minutes in the water bath at 37°C , 0.10 cc of 0.025M calcium chloride is squirted in from a tuberculin syringe, and the time of clotting observed while the mixture is constantly agitated with a wire loop. The standardization curve relating the prothrombin time with the prothrombin concentration in percentage is obtained by plotting the observed prothrombin times against the percentage of normal plasma in the normal plasma-barium-sulfate plasma mixtures.

Determination of prothrombin concentration of the test plasma Of the test plasma 0.10 cc is mixed with 0.90 cc of fresh (no more than five hours old) normal plasma treated with barium sulfate as described above, 0.1 cc of the mixture is added to a thromboplastin tube, and calcium chloride solution added as described above. From the observed prothrombin time of the mixture, the percentage prothrombin is interpolated from the standardization curve. This value, multiplied by 10 to correct for the 1:10 dilution, gives the prothrombin concentration of the undiluted plasma in percentage of normal.

For extremely hypoprothrombinemic plasma a smaller dilution may be necessary (0.4 cc of test plasma to 0.6 cc of barium sulfate plasma). Under such conditions the appropriate dilution correction must be made.

Determination of prothrombic activity In the determination of prothrombic activity on undiluted plasma, the procedure is the same, omitting dilution with barium sulfate plasma. The results are similarly interpolated from the standardization curve described above, and are expressed as prothrombic activity in percentage of normal.

Determination of serum prothrombic activity To 0.7 cc of barium sulfate normal plasma 0.3 cc of oxalated serum, incubated at 37°C for half an

*Note in Figure 3 the differences in degree and duration of dicumarol action in relation to size of dose per kilogram of body weight.

†In man dicumarol is given exclusively by the oral route.

‡Little is known regarding prothrombin synthesis or dicumarol elimination, both of which can conceivably be greatly influenced by the underlying disease or its complications.

§All plasmas are from blood oxalated with 1 cc. of 0.1M sodium oxalate to 9 cc. of blood.

hour to inactivate thrombin, is added. The prothrombin time is determined on 0.1 cc of the mixture in the usual manner, the result interpolated from the standard curve, and the dilution correction applied.

SUMMARY

The available methods for determination of plasma prothrombin are scrutinized in the light of recent advances in knowledge of prothrombin, its activators and accelerators, and its role in the coagulation of blood. Since several nonprothrombin components as well as prothrombin have a profound effect on the velocity of thrombin evolution from prothrombin or on the amount formed and available for clotting fibrinogen, great caution must be exercised in drawing conclusions regarding actual prothrombin concentrations from one-stage prothrombin times or from two-stage prothrombin determinations.

Other weaknesses and limitations of prothrombin methods are discussed, the aims and orientation of the physician are considered, and the most satisfactory clinical laboratory method for prothrombin determination is described.

PARTIAL URETERAL OBSTRUCTION*

Its Effect on Urinary Excretion

GEORGE J WARREN, M.D.,† AND JOSEPH M LOONEY, M.D.‡

WEST ROXBURY, MASSACHUSETTS

A PATIENT with a unilateral ureteral stricture afforded an unusual opportunity to observe the effects of partial obstruction on urinary excretion and the changes in excretion subsequent to its relief. The stricture followed a ureterolithotomy done in the presence of marked infection of the ureter and kidney above the level of the obstructing calculus. A brief report of this case follows.

W S D, a 49-year-old white salesman, was admitted to the West Roxbury Veterans Hospital in October, 1947, for the third time with symptoms of frequency, nocturia and a persistent dull ache in the right flank.

This illness had begun 2½ years previously, when he had been studied at this hospital for total hematuria of 3 days' duration. The hematuria had subsided at the time of entry to the hospital. An x-ray film of the abdomen had revealed

The third admission occurred approximately 6 months after the ureterolithotomy with drainage. In the interim he had been fairly well but had recently noted a loss of energy, some burning on urination, frequency and nocturia. There had been no episodes of fever or acute pain in the right flank.

Physical examination showed that the patient was not in acute distress. There was a well healed, right subcostal scar. There was no costovertebral-angle tenderness. The voided urine was cloudy and contained numerous pus cells. There was no residual bladder urine. Retrograde ureteral catheterization revealed an impassable obstruction in the right ureter at the level of the previous surgical incision. There was considerable hydronephrosis and hydroureter above.

The temperature and pulse were normal, and the blood pressure was 145/95.

Studies of the blood showed a calcium of 10.2 mg, phosphorus of 2.8 mg, uric acid of 3.9 mg and total protein of 7.33 gm per 100 cc. The alkaline phosphatase was 2.0 Bodansky units. A culture of the bladder urine showed the presence of *Aerobacter aerogenes*.

TABLE 1 Preoperative Study

several opacities in the region of the right kidney, but the patient had refused further investigation and had been discharged without a complete study.

In March, 1947, he was admitted to the hospital for the second time. There had been no major urinary symptoms during the 2 years between the first and second admissions. At this second admission he complained of severe pain in the right flank of several days' duration. He was acutely ill and had marked tenderness in the right costovertebral angle. Studies revealed a semiopaque calculus in the upper right ureter. At operation a stone located approximately 8 cm below the ureteropelvic junction was removed. Because of marked infection of the ureter, T-tube drainage of the ureter and kidney was instituted. The tube was removed 2 weeks later, after several days of urinary leakage, the wound became dry and healed, and the patient was discharged in June, 1947. On analysis the calculus was found to be of the mixed type.

On November 14 the right upper ureter was explored. The ureter was imbedded in extensive scar tissue, and approximately 8 cm below the ureteropelvic junction there was a dense stricture, which did not admit the tip of a small duct probe. The ureter above was moderately dilated. A small segment of ureter containing the stricture was excised, and an end-to-end anastomosis performed over the upper arm of a T-tube, which was brought out at the lower angle of the incision. The tube was removed 6 weeks after operation. The fistulous tract healed rapidly, without urinary leakage, and the patient was discharged in December, free of symptoms.

Before the second operation studies were made of the urinary excretion from each kidney. An open-ended No. 6 Fr catheter was passed up each ureter. These were used so as to tamponade the ureteral walls and thereby direct the entire volume of urine through the collecting catheters. The left catheter was passed to the renal pelvis. There was obstruction to the passage of the right catheter at the level of the stricture, and the tip of the instrument appeared to have fixed itself within the stricture site. The flow from both catheters was free and abundant. Specimens were collected in test tubes of equal size. By observation of the levels of urine in each test tube at regular intervals, it was noted that

‡Director of clinical laboratory, Veterans Administration Hospital.

approximately equal quantities of urine were being excreted by each kidney. By such a rough estimation it was assumed that the volume excretion per minute of the affected right kidney closely paralleled that of its normal mate. The amounts of uric acid, calcium, phosphorus and phenolsulfonephthalein were determined. There was a distinct difference in the quantities of these substances excreted in the urine from the right and left kidneys. The results of the analysis of each specimen are given in Table 1. Values are recorded in milligrams per 100 cc. The quantitative phenolsulfonephthalein is given in milligrams per cubic centimeter

The same studies were made on a control subject with a normal upper urinary tract. The patient was a young man who had been admitted to the hospital for investigation of long-standing enuresis. Individual urine specimens were obtained from him during the course of the examination. Blood chemical values were within normal limits throughout. The several values recorded for each kidney of a normal control subject closely paralleled one another. The figures for each kidney are given in Table 3.

DISCUSSION

Final conclusions cannot be drawn from observations on a single case. However, the findings in this case suggest several points of interest when compared with the results of studies made by others. The excretion of normal urine is directly dependent upon the functional integrity of the tubular system. Hayman¹ and Gamble² state that the excretion of phenolsulfonephthalein and diodrast appears to be primarily a function of the tubules. Of the amounts

FIGURE 1 *Intravenous Urogram Taken before Ureteroplasty*

It is interesting to note that the chemical values recorded for the affected right kidney were strikingly lower than those for the normal left kidney, even though the volume of urine excreted was the same. The only exception was the quantity for calcium, which was even a fraction higher than that on the left.

Six months after the plastic repair of the right ureter these studies were repeated. In addition an intravenous urogram taken before operation (Fig 1) was compared with a direct pyelogram taken 5 weeks after operation (Fig 2). Films taken 6 months after ureteroplasty demonstrated more rapid excretion and a better concentration of the dye in the right kidney (Fig 3).

Postoperatively, both urine specimens were collected from the renal pelvis, since there was no further obstruction to the passage of the No. 6 Fr. catheter up the right ureter. The values obtained showed a more normal relation between the urine excreted from the right and that from the left kidney (Table 2).

It will be noted from Table 2 that the postoperative values recorded for the affected right kidney more closely approximated those for the normal left. Particularly striking were the figures for phenolsulfonephthalein appearance time and quantitative phenolsulfonephthalein. Previously, these values had been zero on the right.

FIGURE 2 *Direct Pyelogram Taken Five Weeks after Operation*

given for functional tests approximately 90 per cent of both phenolsulfonephthalein and diodrast is excreted by the tubular system, and only 10 per cent passes through as glomerular filtrate. When given in test doses the bulk of phenolsulfonephthalein and diodrast is bound by adsorption to the plasma proteins. Because of this link, tubular activity is required to effect a separation and excretion of these plasma-bound substances. In the case presented

above, the fact that preoperatively no phenolsulfonephthalein and very little diodrast were excreted by the affected kidney suggests a greatly altered tubular physiology. The probable cause for this altered function was an increased intrapelvic pressure secondary to partial ureteral obstruction. That this sequence of events—obstruction, back pressure and tubular dysfunction—had occurred is further supported by the successful attempt at restoration of normal tubular function during the six months following operation for relief of the obstruction. This is brought out by comparison of the respective values given in Table 1 and 2. Hinman,³ in his studies on hydronephrosis, has clearly demonstrated the structural changes in the tubules that follow hydronephrosis secondary to complete or partial urinary obstruction. The concomitant and subsequent functional change was shown to be one of gradual dilution and diminution of total volume of urine excreted.

Another observation worthy of note is the variation in the calcium level in the preoperative and postoperative study. Urinary stasis, secondary to obstruction of whatever type, has long been recognized and accepted as a definite predisposing factor in the formation and in the recurrence of renal calculi. Higgins,⁴ in discussing factors in the recurrence of renal calculi, noted that many recurrences followed a previous ureterolithotomy. Of these, a significant percentage of cases showed a secondary stricture at the operative site. Rolnick and Singer,⁵ working with dogs in a study of the effects of overdistention of the renal pelvis and ureter, demonstrated the structural damage that can occur to both medulla and cortex with various degrees of increased intrapelvic pressure. They noted also that in the urine from a blocked kidney there was a distinct diminution of the chloride content and an increase in the urea content as compared with the unobstructed side. Since the majority of calculi contain calcium to a greater or lesser degree, the urinary

ciated with an increased urinary calcium, a lowered calcium output was noted in kidneys with marked pathologic changes. This observation suggests that stone-forming tendencies are greater early in the

FIGURE 3 Urogram Taken Six Months after Operation

course of disease of the tubular system than in the irreversible or decompensated stage. Hunner,⁷ in 1924, noted the frequency of ureteral calculi in cases with proved ureteral stricture. In a later

TABLE 2 Postoperative Study

KIDNEY	URIC ACID	PHOSPHORUS	CALCIUM	pH	PHENOLSULFONEPHTHALEIN		CULTURE

Left	6.5	56.7	9.31	5.6	312	0.0425	<i>A. aerogenes</i>

excretion of this element is of particular interest. A stone-forming kidney probably excretes a greater amount of calcium salts than a normal one. Flocks,⁶ in 1939, reported analyses of individual urine specimens taken from "stone-bearing" kidneys and their normal mates. Values for urinary calcium were found to be greater in the stone-forming kidneys. Furthermore, the study revealed that a slight pathologic change in the kidney was usually asso-

ciated with an increased urinary calcium, a lowered calcium output was noted in kidneys with marked pathologic changes. This observation suggests that stone-forming tendencies are greater early in the

paper he⁸ emphasized the role of urinary stasis as a major etiologic factor in calculi in the upper urinary tract. In the majority of studies, attention has been directed to local conditions as possible causes of renal stones, but consideration must be given to systemic conditions as well. The frequent occurrence of uric acid, and occasionally cystine stones, indicates something other than local factors in such patients. Al-

bright et al,⁹ in an extensive study on hyperparathyroidism, clearly showed the direct relation of this systemic disease to frequent and recurrent formation of renal calculi in patients with surgically proved parathyroid tumors or hyperplasia. The systemic disturbance in the metabolism of calcium and phosphorus results in an increased excretion of these elements in the urine. A calculous nidus in the kidney, being constantly bathed in a highly concentrated solution of these substances, will have ideal conditions for the gradual formation of a calculus. Such patients usually exhibit bilateral stones either concurrently or alternately.

In most patients the formation of unilateral recurrent calculi cannot be explained on the basis of

of the right kidney in the case presented, preoperatively, the probability of a nephrectomy was considered. The finding of a short, partially obstructing stricture at operation prompted the course of treatment employed. That this procedure was justified is evidenced by the structural and functional improvement of the affected kidney in the six months following operation.

SUMMARY

A study on partial ureteral obstruction and its effect on urinary excretion is presented. Quantitative analyses of uric acid, phosphorus, calcium and phenolsulfonephthalein in the urine specimens from a partially obstructed kidney and its normal mate

TABLE 3 Control Study

KIDNEY	URIC ACID	PHOSPHORUS	CALCIUM	PH	PHENOLSULFONEPHTHALEIN		CULTURE

systemic disease alone. In these patients, who show no evidence of systemic disease, local factors appear to be responsible for the calculi. The exact mechanism of the process is obscure. Of the many recognized entities, urinary stasis and back pressure seem to be highly significant ones. In a decompensating or decompensated kidney, resulting from back pressure, the tubular physiology is greatly altered. In the case reported above, there was definite evidence of disturbed tubular function as shown by the failure of the affected kidney to excrete phenolsulfonephthalein and diodrast preoperatively. Furthermore, the wide variation in the amounts of other substances excreted is further evidence of tubular dysfunction. Despite this apparent failure of the tubular system the amount of calcium excreted was slightly higher than that of its normal mate. These findings suggest the possible relation of abnormal tubular physiology to the formation of renal stones.

Another point brought out by this case study is that regarding the value of reconstructive surgery to conserve renal tissue. Dodson¹⁰ has reported a large series of cases in which corrective surgery has resulted in the reconstruction of relatively good structural and functional kidneys. Because of the structural distortion and marked loss of function

were made. It was found that there was a marked diminution in the excretion of all these elements except calcium in the urine from the affected kidney. This wide variation disappeared after relief of the obstruction. Inferences regarding altered tubular function and increased tendency to stone formation are drawn from the data presented. Early recognition and treatment of obstructing lesions of the urinary tract may obviate the subsequent occurrence of a more serious disease.

MUMPS COMPLICATED BY MYOCARDITIS, MENINGOENCEPHALITIS AND PANCREATITIS

Review of the Literature and Report of a Case

JOHN H. BLAND, M.D.*

BURLINGTON, VERMONT

MUMPS is usually considered to be an acute systemic disease of specific viral etiology with a special predilection for the parotid glands. The common complications are orchitis, pancreatitis, oophoritis, mastitis and meningitis or meningoencephalitis, or both. Myocarditis has until the past few years been considered a rare and unusual complication. Several studies recently made call attention to the occurrence of myocarditis during the convalescent course of epidemic parotitis.

It is the purpose of this paper to submit a case report as additional evidence to support the belief that mumps is a generalized infectious process and that the myocardium and pericardium may be involved by an acute, infectious process of viral etiology, such affections may occur with varying frequency and may be of any varying severity. A discussion of the importance and implications of the studies made in the past few years is offered.

Pujol¹ first suggested in 1918 that myocarditis might be a complication of mumps. He reported 3 cases, each of which manifested clinical evidence of myocardial involvement, however, he lacked electrocardiographic confirmation. In 1925 Barbato² suspected mumps myocarditis on the basis of clinical observation. Manca,³ in 1932, was the first to report pathological sections in a case of acute, interstitial, fibrinous myocarditis occurring in a fatal case of mumps. He believed that this was a typical tissue reaction to the mumps virus. Wesselhoeft⁴ reviewed progress in mumps in 1942 and at that time noted the evidence of its being a systemic disease with a predilection for certain tissues. He remarked on the frequency with which clinical and subclinical mumps meningoencephalitis was unrecognized. The complement-fixation test for mumps virus on cerebrospinal fluid or blood serum and the dermatologic sensitivity test of Enders and his co-workers⁵ were discussed. Wendkos and Noll,⁶ in 1944, reported a case of mumps myocarditis diagnosed only by a chance electrocardiogram. They noted minor T-wave changes, bradycardia and lengthened PR interval, which was clearly temporarily shortened by atropine as is first-degree heart block secondary to active rheumatic carditis. Rosenberg⁷ reported an epidemic study in which electrocardiographic evidence of cardiac involvement was noted in 16 of 104 cases of mumps, or

15 1/2 per cent. Changes in the tracings (done serially) all occurred between the fifth and tenth days of illness, and returned to normal in from two to thirty-five days. Only 4 of the 16 patients had clinical evidence of cardiac involvement. Seven of the 16 had acute orchitis as a complication. This author points out how the implications reached pertain to rheumatic fever. He suggests that in the majority of cases mumps myocarditis follows a subclinical course and requires electrocardiographic studies for its recognition. He noted changes of varying magnitude in all complexes, but no specific pattern was noted. Fellnor and Pullen⁸ added another case with clinical and electrocardiographic evidence of myocarditis. There are many reports, such as that of Holden, Eagles and Stevens,¹⁰ describing central-nervous-system involvement in mumps. Bruenn¹¹ has reported on the mechanism of impaired auriculoventricular conduction in acute rheumatic fever, and Keith¹² studied overstimulation of the vagus nerve in rheumatic fever, emphasizing the nonspecific nature of PR-interval prolongation. Saphir¹³ reported myocarditis in bronchiectasis and noted the discrepancy between pulse rate and a slight elevation of temperature. The PR interval has been reported prolonged in other acute infectious diseases such as pneumonia, scarlet fever, diphtheria and measles.

The following case is reported as an instance of a complication of mumps and as additional evidence that the infection is a generalized disease.

CASE REPORT

J. H., a 55-year-old man, was admitted to the hospital on June 2, 1947, with a history of epigastric discomfort and a sense of expanding pressure, high in the epigastrium, of 2 days duration. This was exaggerated by effort, but was described as "indigestion." In about 2 hours marked nausea, vomiting and extreme weakness, which lasted 48 hours, followed. The patient vomited or retched every 15 or 20 minutes during this time. On the first night of the illness he was unable to lie flat in bed because of a choking sensation and dyspnea, relieved by sitting up on the edge of the bed. He complained of marked apprehension. Two episodes of syncope of 1 or 2 minutes' duration occurred on the day of admission. (This had never happened before.) He had chilly sensations and reported that he had a temperature of 102°F. He came to the hospital because of the dyspnea, which interfered with his work as a refrigerator repairman. On the day of admission, he developed a severe pulsating headache, located in the vertex, which continued for 5 days and finally subsided spontaneously. The patient was very lethargic and mildly disoriented. Marked anorexia was present for many days.

A careful review of the systems was not helpful. The past medical history disclosed nothing significant, and the family

*Fellow in cardiovascular research, University of Vermont College of Medicine.

bright et al,⁹ in an extensive study on hyperparathyroidism, clearly showed the direct relation of this systemic disease to frequent and recurrent formation of renal calculi in patients with surgically proved parathyroid tumors or hyperplasia. The systemic disturbance in the metabolism of calcium and phosphorus results in an increased excretion of these elements in the urine. A calculous nidus in the kidney, being constantly bathed in a highly concentrated solution of these substances, will have ideal conditions for the gradual formation of a calculus. Such patients usually exhibit bilateral stones either concurrently or alternately.

In most patients the formation of unilateral recurrent calculi cannot be explained on the basis of

of the right kidney in the case presented, preoperatively, the probability of a nephrectomy was considered. The finding of a short, partially obstructing stricture at operation prompted the course of treatment employed. That this procedure was justified is evidenced by the structural and functional improvement of the affected kidney in the six months following operation.

SUMMARY

A study on partial ureteral obstruction and its effect on urinary excretion is presented. Quantitative analyses of uric acid, phosphorus, calcium and phenolsulfonephthalein in the urine specimens from a partially obstructed kidney and its normal mate

TABLE 3 Control Study

KIDNEY	URIC ACID	PHOSPHORUS	CALCIUM	pH	PHENOLSULFONEPHTHALEIN		CULTURE
	mg / 100 cc	mg / 100 cc	mg / 100 cc		APPEARANCE TIME min	QUANTITATIVE TEST mg / cc	
Right	45.6	18	28.9	4.5	5	0.49	Sterile
Left	46.2	16.5	29.7	4.5	5	0.50	Sterile

systemic disease alone. In these patients, who show no evidence of systemic disease, local factors appear to be responsible for the calculi. The exact mechanism of the process is obscure. Of the many recognized entities, urinary stasis and back pressure seem to be highly significant ones. In a decompensating or decompensated kidney, resulting from back pressure, the tubular physiology is greatly altered. In the case reported above, there was definite evidence of disturbed tubular function as shown by the failure of the affected kidney to excrete phenolsulfonephthalein and diodrast preoperatively. Furthermore, the wide variation in the amounts of other substances excreted is further evidence of tubular dysfunction. Despite this apparent failure of the tubular system the amount of calcium excreted was slightly higher than that of its normal mate. These findings suggest the possible relation of abnormal tubular physiology to the formation of renal stones.

Another point brought out by this case study is that regarding the value of reconstructive surgery to conserve renal tissue. Dodson¹⁰ has reported a large series of cases in which corrective surgery has resulted in the reconstruction of relatively good structural and functional kidneys. Because of the structural distortion and marked loss of function

were made. It was found that there was a marked diminution in the excretion of all these elements except calcium in the urine from the affected kidney. This wide variation disappeared after relief of the obstruction. Inferences regarding altered tubular function and increased tendency to stone formation are drawn from the data presented. Early recognition and treatment of obstructing lesions of the urinary tract may obviate the subsequent occurrence of a more serious disease.

LEFT VOCAL-CORD PARALYSIS ASSOCIATED WITH HYPERTENSIVE HEART DISEASE

WILLIAM C L DIEFENBACH, M D *

ALBANY, NEW YORK

LEFt vocal-cord paralysis is frequently observed in various forms of intrathoracic disease, such as aortic aneurysm, mediastinal tumors, pleuritic thickening and pulmonary tuberculosis. A variety of cardiac lesions, including mitral stenosis, arteriosclerotic heart disease, congenital heart disease and aneurysms of the large vessels, may also produce this syndrome. Its occurrence in only a small percentage of cardiac conditions is not clear.

Although a number of hypotheses have been proposed, the exact mechanism has not been elucidated. Ortnor,¹ in 1897, first described vocal-cord paralysis associated with heart disease, his 2 cases occurring in mitral stenosis. At autopsy an enlarged auricle was reported to have caused compression of the recurrent laryngeal nerve against the aorta. In 1904 Alexander² was the first to advance the theory that the pulmonary artery by its own enlargement, or indirectly by enlargement of the left auricle, is pressed against the nerve and the arch of the aorta. Frischauer,³ in 1905, found the nerve compressed between the aorta and left pulmonary artery by the pressure of a dilated left auricle and pulmonary vein. Fetterolf and Norris⁴ (1911) reviewed 37 cases and, after careful anatomic studies of frozen specimens, concluded that dilatation of the left auricle caused the left pulmonary vein to press against the pulmonary artery, the latter in turn being forced against the aorta. It was their belief that the nerve paralysis was due to actual compression between the left pulmonary artery and aorta or ligamentum arteriosum. Kraus⁵ suggested that in mitral stenosis the right ventricular dilatation caused a displacement of the heart to the right, with consequent dragging on the aortic ligament and resultant stretching and paralysis of the nerve. Guttman and Neuhof⁶

observed that the nerve may also be compressed and incorporated between bands of pericardial and mediastinal adhesions, this occurred in a case of theirs in which pericarditis was present. Careful anatomic studies by Dolowitz and Lewis⁷ demonstrated that the lymph nodes in the triangle formed by the pulmonary artery, aortic arch and ligamentum arteriosum might effectively compress the left recurrent laryngeal nerve when accompanied by cardiac hypertrophy or pulmonary-artery engorgement, or both. Other authors have suggested that the cicatrization occurring in sclerosis, thrombosis and atheromas of the pulmonary artery may be contributing factors. Emphasis has been placed upon dilatation of the pulmonary vessels which may be apparent by fluoroscopy but may not be observed at autopsy.

The paralysis may occur at any time and is manifested by changes in the voice, which becomes hoarse and indistinct. The patient may be able to speak in a whisper. Laryngoscopy shows anything from a complete paralysis to sluggish movement of the vocal cord on the left side. The nerve is usually affected slowly by the gradual enlargement of the surrounding structures without marked accompanying cardiac symptoms, or it may be paralyzed rather suddenly during a sudden decompensation in a chronic case. Not infrequently there are relapses or recurrences of the paralysis of the left recurrent laryngeal nerve. In some cases the voice disturbance may be the first symptom that leads the patient to consult a physician. If the pressure has not been too severe or too prolonged, function will return with the removal of the cause. The prognosis in these cases is that of nerve injury from pressure in general.

CASE REPORTS

CASE 1. G. G. (A. H. 74076), a 61-year-old widowed sand blaster, came to the Outpatient Clinic of the Albany Hospital

*Assistant in medicine, Albany Medical College; assistant resident in medicine Albany Hospital.

history revealed only that a sister had died of pulmonary tuberculosis in 1912. The patient was not a heavy smoker and did not drink inordinately.

Physical examination disclosed a middle-aged man lying quietly in bed. He was moderately apprehensive. There was mild bulbar conjunctival injection. The peripheral vessels were tortuous, but not difficult to compress. The ocular fundi showed Grade I arteriosclerosis. The neck was supple. The chest was of an emphysematous type and the lung fields were clear. The heart sounds were very distant and difficult to hear. An arrhythmia was present that was interpreted as representing premature beats. The point of maximum impulse could not be palpated. No murmurs were heard. The abdomen was normal except for marked deep epigastric tenderness, pressure causing the lethargic patient to cry out. Peristalsis was readily heard. The extremities were normal. Neurologic examination was negative except for mild disorientation.

The temperature was 102°F, the pulse rate 64, and the respirations 22, the blood pressure in both arms was 120/78. Examination of the blood disclosed a red-cell count of 5,200,000, with a hemoglobin of 16.8 gm., and a white-cell count of 4200, with 61 per cent neutrophils and 39 per cent lymphocytes. Urinalysis was negative. The serum amylase was 147 units, the cephalin flocculation test was + in 24 and +++ in 48 hours. The sedimentation rate (Wintrobe method) was 8 mm. per hour. The blood urea nitrogen was 14.8 mg. per 100 cc. The cerebrospinal fluid contained 516 leukocytes per cubic millimeter, with 185 polymorphonuclear cells and 331 lymphocytes, a total protein of 63.3 mg., glucose of 63.3 mg. and chloride of 736.7 mg. per 100 cc.

A teleroentgenogram was normal, but electrocardiograms manifested a decreased voltage of the QRS complexes, frequent auricular premature beats and sinoauricular block with ventricular escape beats. The T wave in Lead 3 was of greater amplitude than that of Lead 1, which was considered probably abnormal, but the concomitant amplitude discrepancy in the QRS complexes of the same leads makes this equivocal. The very small R wave with a deep S wave in Lead CF₄ is also abnormal suggesting some myocardial disturbance in the lateral wall of the left ventricle.

The patient was treated with ordinary analgesics, and a tentative diagnosis was made of central-nervous-system viral infection of unknown type. Five days after admission a characteristic acute parotitis on the right, with swelling, tenderness and inflamed right parotid-duct orifice, rapidly developed. The serum amylase at this time was 22.4 units.

The subsequent course was uneventful, the temperature falling by lysis in 8 days, with a gradual disappearance of symptoms. Cerebrospinal-fluid studies later revealed a gradual return to normal limits. Cultures of blood and cerebrospinal fluid were repeatedly negative. Sixteen days later an electrocardiogram disclosed none of the conduction defects noted above, although the discrepancy in the T waves in Leads 1 and 3 and the absence of a normal R wave in Lead CF₄ persisted. The patient was discharged 37 days after admission, when he felt perfectly well. He was seen 6 months later and was still well, with no suggestion of sequelae.

DISCUSSION

Unequivocal meningoencephalitis, as diagnosed by clinical and laboratory methods, was present in this case. A diagnosis of acute pancreatitis was thought justified in view of the sudden onset of violent nausea and vomiting persisting for forty-eight hours, the definite though subjective evidence of marked tenderness deep in the epigastrium and the sense of expanding epigastric pressure that did not radiate. The change in serum amylase may or may not have been significant. The patient had marked apprehension and orthopneic symptoms, which were followed by two episodes of sudden, unpredictable syncope with unconsciousness lasting one or two minutes, the electrocardiographic changes of decreased QRS complex, premature auricular contractions and ventricular escape suggested some

interference with origin of the auricular impulse or poor auriculoventricular conduction. He also had dyspnea on the day of his admission while engaged in refrigerator-repair work, not a strenuous occupation. All this suggests imminent left-ventricle failure, as well as some degree of transient auriculoventricular or sinoauricular heart block. It was believed that these findings justified a diagnosis of myocarditis.

An etiologic diagnosis was not reached until the patient later developed acute right parotitis. Mumps can so readily explain the entire chain of events despite the unusual sequence that the patient was considered to have had the mumps virus, which had manifested its pathologic changes in the central nervous system, pancreas, heart and right parotid gland. The widespread distribution suggested blood-stream spread.

The case presented and the review of the literature strongly suggest that mumps myocarditis goes frequently unrecognized and usually manifests itself in a subclinical form. The importance of its recognition is that with the knowledge of its presence, one is more inclined to prolong the convalescence to prevent the occurrence of myocardial residua in the event of extensive involvement. Apparently, there are no residua, and the process is completely reversible in the vast majority of cases, though reversal may be delayed by failure to recognize its presence. It seems worth while to suggest the use of the complement-fixation test and the intradermal skin test of Enders,⁵ as a diagnostic aid in an obscure myocarditis. The PR-interval changes discussed in the literature make the specificity of such changes in rheumatic fever a matter of conjecture. Wendkos and Noll⁶ showed that the PR-interval prolongation of mumps myocarditis is shortened by atropine sulfate, as is the prolonged PR interval of acute rheumatic fever. The non-specific nature of this electrocardiographic change should be appreciated. Though a PR interval may be within usual normal limits for the age of a patient, one should keep in mind that a tracing taken after recovery may show a much shorter PR interval, which is actually normal for the particular patient.

Rosenberg^{7, 8} has stressed the fact that mumps myocarditis is probably not rare and has ably presented the implications of work done thus far and the importance of further study. Inasmuch as mumps is frequently not reported, a statistical study is difficult to accomplish and electrocardiographic study in all acute infectious diseases might well prove fruitful whenever such a program is feasible.

SUMMARY

A case in which mumps was complicated by myocarditis, meningoencephalitis and pancreatitis is presented.

TORSION OF THE NORMAL FALLOPIAN TUBE COMPLICATING PREGNANCY*

Report of a Case

RENWICK K. CALDWELL, M.D.†

NORTHFIELD, VERMONT

BECAUSE torsion of the normal fallopian tube is a rare complication of pregnancy, the following case is added to those already on record

Mrs. J. B., a 23-year-old primigravida, was admitted to the hospital on July 30, 1948. Eleven days previously she experienced her first attack of pain in the right anterior portion of the abdomen. This pain began without a known precipitating cause, had no localizing signs or symptoms and disappeared when the patient remained in the upright position for 20 minutes. After this episode and until 2 days before admission, the pain recurred daily, appearing occasionally in the right flank as well as in the right anterior portion of the abdomen. Three days before admission the patient noted intermittent urinary frequency. White cells were found in the sediment on microscopic examination of the urine. After a day without discomfort and on the day preceding admission the pain reached its maximum severity, and an area of right-lower-quadrant tenderness was noted for the first time.

The patient's last menstrual period had begun on February 6, and the estimated date of confinement was November 13. Except for morning sickness controlled by intravenous injections of thiamine hydrochloride and pyridoxine hydrochloride, the pregnancy had been uneventful. The past and family histories were noncontributory.

Examination of the blood disclosed a white-cell count of 11,600. Except for 28 per cent immature neutrophils, the differential count was normal.

Because of the urinary frequency and pyuria cystoscopy was done. There were no abnormal findings. After the cystoscopy, and because of the persistence of the right-lower-quadrant pain, a laparotomy was performed.

Under general anesthesia the abdomen was opened through a right-rectus incision. The uterus was enlarged to a size consistent with a 5 or 6 months' pregnancy. The right ovary was located, and beneath it was a dark mass roughly 4 by 3 cm. This mass was elevated and, by untwisting, was found to consist of the terminal two thirds of the right fallopian tube, which then resumed its normal position. The demarcation between the normal and hemorrhagic areas of the fallopian tube was definite, and the nonviable portion of the tube was removed with ease. To avoid premature termination of the pregnancy, manipulation of the uterus was kept at a minimum. The appendix, which appeared normal, was not removed.

The immediate postoperative course was marked by a gradual diminution of the pain. Discharge from the hospital was delayed by slow healing of the skin wound.

Since leaving the hospital the patient has been free of pain, and the pregnancy has progressed normally.

On pathological examination† the specimen consisted of a dark-brown mass of tissue 4 by 3 by 2 cm. On cut section

there was a soft, red-brown and brown surface with one cystic space approximately 1 cm in diameter. On microscopical examination the tube, lumen and wall were filled with red blood cells. The epithelium was largely destroyed, and that which remained was low columnar. It appeared that the congestion and hematosalpinx followed the torsion of the tube.

The rarity of torsion of the normal fallopian tube during pregnancy has been noted. McKerrow¹ reported such a case with involvement of the right tube, and Sheldon² discussed a case in which both the right tube and ovary had undergone complete torsion and become gangrenous. Two additional articles have appeared in recent years in foreign-language journals. Torsion of the tube after hematosalpinx is somewhat more common, and Savage,³ in 1936, reported such a case and gathered 13 similar cases from the literature.

Because of the infrequent occurrence of this complication, the diagnosis is not made until operation. The majority of cases of torsion of the fallopian tube, normal or otherwise, during pregnancy have involved the right tube. In these cases the preoperative diagnosis of acute appendicitis was frequent and logical. In McKerrow's¹ case and that reported above there were findings suggestive of genitourinary disease, but in both cases cystoscopic examination was negative. Ovarian cyst with twisted pedicle, ectopic pregnancy in the fallopian tube and hydro-salpinx are other possible preoperative diagnoses.

SUMMARY

An additional case of torsion of the normal fallopian tube during pregnancy is reported. This rare complication is diagnosed correctly by laparotomy.

†Physician, Green Mountain Clinic, attending physician, Mayo Memorial Hospital.

‡Performed at Dartmouth Medical School, Hanover, New Hampshire.

on May 5, 1948, with signs and symptoms of severe congestive failure. For 7 months prior to admission there had been progressive weakness, hoarseness, dyspnea, orthopnea, ankle edema, palpitation and precordial distress. During this time there were also episodes of left-sided chest pain, associated with a cough productive of small amounts of frothy blood-streaked sputum.

Aside from appendicitis and gonorrhea the past history was not significant. The family history was noncontributory.

Physical examination revealed the patient to be markedly dyspneic and orthopneic, with some cyanosis of the lips and nail beds. The fundi showed arteriovenous nicking and tortuosity and narrowing of the arteries. The neck veins were distended. Percussion of the chest revealed dullness over the left base posteriorly with absent breath sounds over this area. Moist rales were heard throughout both lung fields. On percussion the border of cardiac dullness extended to the left anterior axillary line, and the point of maximal impulse was located in the sixth intercostal space. The rhythm was totally irregular, and the sounds were of poor quality. No murmurs were heard. The abdomen was slightly distended, and the edge of the liver, which was firm and smooth, was palpated 4 cm. below the right costal margin. There was pitting edema of the lower extremities extending above the knees.

The temperature was 100.8°F, the pulse 106, and the respirations 28. The blood pressure was 250/140.

The urine was normal. Examination of the blood disclosed a hemoglobin of 14 gm., and a white-cell count of 12,000, with 94 per cent neutrophils. The fasting blood sugar was 123 mg., and the nonprotein nitrogen 46 mg. per 100 cc. The blood Wassermann reaction was negative.

A roentgenogram of the chest showed the heart to be enlarged. There was diminished transmission of rays through the left side of the chest, with displacement of the cardiac shadow to the right, suggesting effusion.

An electrocardiogram revealed auricular fibrillation and left-axis deviation, with left ventricular hypertrophy and strain. There was also evidence of myocardial damage.

A clinical diagnosis of hypertensive heart disease, with decompensation, auricular fibrillation and multiple pulmonary emboli with pleural effusion, was made.

The patient improved after treatment with bed rest, oxygen, diuretics, 1-gm. sodium diet, digitalis and dicumarol. Thoracentesis was performed twice, and neither the hemorrhagic pleural fluid nor the sputum showed tubercle bacilli or tumor cells.

On the 15th hospital day laryngoscopy demonstrated sluggish movement of the left vocal cord. As the patient continued to improve the heart decreased in size, and on the 31st hospital day he was discharged. His hoarseness had improved, and when he was seen again in the Medical Out-patient Clinic 3 months later it had cleared completely.

CASE 2. M. S. (A. H. 48565), a 50-year-old housewife, came to the Albany Hospital for the first time on July 15, 1938, with signs and symptoms of severe congestive failure. For 6 months prior to admission there had been progressive dyspnea, ankle edema, orthopnea and weakness.

The past history was significant only in that she had had hypertension since her third pregnancy in 1931. The family history was noncontributory.

Physical examination showed the patient to be in severe congestive failure with a blood pressure of 240/120. After treatment and study a clinical diagnosis of hypertensive heart disease with decompensation and auricular fibrillation was made. She was discharged improved on the 20th hospital day to be followed in the Outpatient Clinic.

Since that first admission she has been hospitalized ten times for similar episodes of decompensation. Of particular interest has been the gradual increase in the size of the heart, which on x-ray study has shown an increase of 7 cm. within the past 4 years.

Hoarseness developed rather suddenly on October 11, 1945, and has persisted to date. Laryngoscopy showed complete paralysis of the left vocal cord. In view of the long-standing

decompensation with marked cardiac enlargement the prognosis regarding the hoarseness is poor.

DISCUSSION

These are 2 typical cases of vocal-cord paralysis associated with heart disease. When a patient with a cardiac lesion complains of hoarseness and laryngoscopy is confirmatory, paralysis of the left recurrent laryngeal nerve must be suspected as being due to pressure on the nerve. With the institution of proper therapy, if successful, the paralysis disappears. The condition in Case 1 responded satisfactorily to therapy, in Case 2 hoarseness appeared suddenly, and with the progressive cardiac hypertrophy and dilatation in spite of therapy, the paralysis is now complete and permanent.

SUMMARY

Left vocal-cord paralysis is frequently observed with various forms of intrathoracic disease. A variety of cardiac lesions may also produce this syndrome. The theories of the mechanism involved are summarized.

Two cases of hypertensive heart disease with vocal-cord paralysis are presented.

These treatment schedules are technically more difficult to administer, and the likelihood of reactions is inescapably higher. The co-operation of patients would obviously be difficult to obtain in many cases.

Arsenotherapy

Reports of intensive treatment of early syphilis with triweekly injections of mapharsen and concomitant weekly injections of bismuth continue to appear.⁵⁷⁻⁵⁸ These are follow-up studies of rapid treatment schedules that were in the course of development just prior to the advent of penicillin. From nine to fifteen weeks were required to complete these schedules. The results were good, with as high as 90 per cent satisfactory cumulative percentage by the end of three years. Serious reactions were infrequent compared to more intensive massive-therapy schedules, but in comparison to penicillin the reaction rate and severity were high.

Relapse as Reinfection

The remarkably successful use of penicillin in the treatment of early syphilis has been clouded to some extent by the difficulty in ascertaining the true percentage of relapses as contrasted to reinfection. The relative ease of cure that is now available is bound to create a greater degree of carelessness among many less responsible citizens. The symptoms of an early infection can be relieved more quickly than the common cold in a large percentage of cases. With slight exaggeration, it might be said that a habitual offender could acquire new infections almost faster than each preceding one was cured. It is thus obvious that differentiating failure of treatment, or syphilitic relapse, and a true reinfection may present the most complicated of problems. For the benefit of absolute accuracy, the rates of failure with treatment as efficient as penicillin should therefore include all patients in a given series who require retreatment within at least the first few months following the initial course of therapy. Rigid criteria for the determination of relapse and reinfection, as practiced in the past, have of necessity been abandoned. Many such differentiations now appear to rest on clinical impressions rather than on certainty. One new set of criteria has been presented that seems to deserve consideration.⁵⁹ It is held that the diagnosis of syphilitic reinfection in persons previously treated for syphilis should require clinical evidence of a second infection preceding the serologic evidence. It is further stated that the response to a second treatment course should be similar both clinically and serologically to that seen with the previous infection. Epidemiologic evidence is held to be of distinct value. Exposure to a person with known infectious syphilitic lesions, followed by the development of the infection after a proper incubation period in the patient under consideration,

is strong evidence of reinfection. Obviously the primary lesion should be a darkfield-positive chancre. The treatment of the preceding infectious episode must certainly have been adequate, or it would point to the likelihood of relapse. A period of seronegativity between the two infectious episodes is highly desirable in the effort to prove reinfection.

LATE SYPHILIS

Less effort has been expended in the treatment of late syphilis with penicillin than any other stage of the disease. The results in late latent syphilis have been discouraging. In cardiovascular disease, the effects of penicillin are questionable. In other active phases of late syphilis, there is more encouragement, but it seems highly questionable whether penicillin alone should be depended upon.

In most forms of late active syphilis it is imperative to avoid Herxheimer reactions. This is particularly vital in visceral disease. Cole⁶⁰ has advocated that all patients with late syphilis receive a course of heavy metal (bismuth) in addition to potassium iodide preceding penicillin therapy to obviate the danger of reactions. This is excellent advice and might well be carried a step farther. A diagnosis of late latent syphilis may be correct as far as it is possible to determine, and yet the patient may have a concealed active lesion. Thus, it is equally appropriate to give a latent case the chemotherapy preceding penicillin.

There is fairly general agreement that late latent syphilis is a field in which penicillin treatment is far from proved in value.⁷⁶⁻⁹³ It is not yet known whether penicillin may be of preventive value in latent syphilis, although the efficacy of traditional chemotherapy has long been accepted in that respect. It will take many years to determine this point. Certainly, one should not rely on penicillin alone in either latent or active late syphilis until far more has been accomplished with this mode of treatment. The suggested dosage schedules in many cases are similar to those recommended for neurosyphilis.

In late cutaneous syphilis moderate doses of penicillin have been striking in their effect.⁷⁶ Not all late gummatous syphilis is responsive to penicillin.⁹⁴ Syphilis of the bone is known to respond satisfactorily to penicillin therapy in most cases.⁷⁶⁻⁹⁵ A word of caution should be interjected regarding these so-called benign forms of late syphilis. Their clinical response to any form of therapy may seem satisfactory, but serologic response is often exceedingly slow and sometimes apparently nonexistent. It must be constantly borne in mind that syphilis is a systemic disease and reliance cannot be placed upon the behavior of any one symptomatic phase of the disorder.

A survey of 550 patients with late syphilis treated by penicillin has appeared from the Johns Hopkins

BROOKLINE, MASSACHUSETTS

Serologic Response

A prolonged follow-up study of the pattern of serologic response after penicillin therapy for early syphilis is of utmost importance. A monthly quantitative test is desirable in all cases and should be performed for probably not less than a year. The quantitative determination of reagin titer at monthly intervals will enable the practicing physician correctly to assay the response to treatment and should warn him of an impending relapse before it becomes clinically manifest. In early syphilis adequate therapy with penicillin will usually reverse positive serologic tests to negative in about six months.⁷⁴ Some patients, especially in the late secondary or early latent stage, may require much longer than six months to become seronegative. Small amounts of reagin in the blood for longer than six months after treatment do not necessarily require retreatment. Conversely, a consistent slow rise in titer should indicate the need for repetition of a course of therapy. If the serum reagin titer does not show a steady and progressive drop during the first six months, another indication for retreatment is presented. These statements apply strictly to early syphilis.

Quantitative serologic examinations in the follow-up study of penicillin-treated syphilis not only are a guide in response to treatment and an aid in predicting an impending relapse but also may serve as a helpful means of differentiating serologic relapse and reinfection.⁸⁰ In relapses there is frequently a sudden sharp increase in serologic titer, after an apparent response to treatment that has not resulted in a completely negative test. Patients who become reinfected have usually attained and maintained complete serum negativity followed by the development of a new primary lesion at a new site with the development of seropositive reaction shortly thereafter. A new chancre should certainly be darkfield positive.

A comparison of the serologic response following penicillin therapy with that following previously established methods has been used to gauge therapeutic efficacy as shown by serologic cure.⁸¹ Two hundred and eight patients with untreated primary or secondary syphilis were hospitalized and treated

with three different schedules of penicillin therapy. The serologic response in these cases was compared with data from a similar series of patients who had been given arsenical treatment. The rate of fall of serum reagin was observed to be comparable in each group, although in some classifications the penicillin response was a little slower. If this is correct, it merely illustrates that the actual efficiency of penicillin is not remarkably greater than that of arsenic, when assayed from this one standpoint.

Combined Therapy

Numerous schemes combining penicillin with bismuth, arsenic, fever and so forth have been studied in a search for a possible ideal adjuvant to penicillin. So far there is no report of greater efficiency or anything like as low a rate of reactions as that seen with penicillin alone. One series of 1350 patients with early syphilis received a combination of mapharsen and penicillin.⁸² After six months' follow-up study, 83.6 per cent were seronegative. The incidence of reactions was high. A small series of cases treated with bismuth and penicillin showed no better results than a control group receiving only penicillin.⁸³ One report is actually pessimistic about penicillin.⁸⁴ Another analysis compares groups of patients treated biweekly or triweekly with mapharsen or neoarsphenamine, massive arsenotherapy, penicillin alone and penicillin combined with arsenoxide and bismuth.⁸⁵ The most rapid response was obtained with arsenoxide twice weekly. The combined penicillin-chemotherapy group was seven weeks slower in serologic response, and the failure rate was approximately 17 per cent.

The combination of penicillin and fever therapy in early syphilis has been studied from the standpoint of increasing the favorable effects of penicillin in a given dosage and also the possibility of shortening penicillin therapy without the loss of efficiency.⁸⁶ The maximum dosage was 1,200,000 units of penicillin over a period of seven and a half days, in addition to three sessions of physically induced fever. The failure rate in this group was a little more than a third lower than that in a comparable group receiving the same amount of penicillin alone, but the result was distinctly less favorable than that after more satisfactory penicillin dosage without adjuvants. Attempts to shorten the penicillin-fever therapy to thirty hours were unsuccessful.

These treatment schedules are technically more difficult to administer, and the likelihood of reactions is inescapably higher. The co-operation of patients would obviously be difficult to obtain in many cases.

Arsenotherapy

Reports of intensive treatment of early syphilis with triweekly injections of mapharsen and concomitant weekly injections of bismuth continue to appear.⁸⁷⁻⁸⁸ These are follow-up studies of rapid treatment schedules that were in the course of development just prior to the advent of penicillin. From nine to fifteen weeks were required to complete these schedules. The results were good, with as high as 90 per cent satisfactory cumulative percentage by the end of three years. Serious reactions were infrequent compared to more intensive massive-therapy schedules, but in comparison to penicillin the reaction rate and severity were high.

Relapse vs Reinfection

The remarkably successful use of penicillin in the treatment of early syphilis has been clouded to some extent by the difficulty in ascertaining the true percentage of relapses as contrasted to reinfection. The relative ease of cure that is now available is bound to create a greater degree of carelessness among many less responsible citizens. The symptoms of an early infection can be relieved more quickly than the common cold in a large percentage of cases. With slight exaggeration, it might be said that a habitual offender could acquire new infections almost faster than each preceding one was cured. It is thus obvious that differentiating failure of treatment, or syphilitic relapse, and a true reinfection may present the most complicated of problems. For the benefit of absolute accuracy, the rates of failure with treatment as efficient as penicillin should therefore include all patients in a given series who require retreatment within at least the first few months following the initial course of therapy. Rigid criteria for the determination of relapse and reinfection, as practiced in the past, have of necessity been abandoned. Many such differentiations now appear to rest on clinical impressions rather than on certainty. One new set of criteria has been presented that seems to deserve consideration.⁸⁹ It is held that the diagnosis of syphilitic reinfection in persons previously treated for syphilis should require clinical evidence of a second infection preceding the serologic evidence. It is further stated that the response to a second treatment course should be similar both clinically and serologically to that seen with the previous infection. Epidemiologic evidence is held to be of distinct value. Exposure to a person with known infectious syphilitic lesions, followed by the development of the infection after a proper incubation period in the patient under consideration,

is strong evidence of reinfection. Obviously the primary lesion should be a darkfield-positive chancre. The treatment of the preceding infectious episode must certainly have been adequate, or it would point to the likelihood of relapse. A period of seronegativity between the two infectious episodes is highly desirable in the effort to prove reinfection.

LATE SYPHILIS

Less effort has been expended in the treatment of late syphilis with penicillin than any other stage of the disease. The results in late latent syphilis have been discouraging. In cardiovascular disease, the effects of penicillin are questionable. In other active phases of late syphilis, there is more encouragement, but it seems highly questionable whether penicillin alone should be depended upon.

In most forms of late active syphilis it is imperative to avoid Herxheimer reactions. This is particularly vital in visceral disease. Cole⁹⁰ has advocated that all patients with late syphilis receive a course of heavy metal (bismuth) in addition to potassium iodide preceding penicillin therapy to obviate the danger of reactions. This is excellent advice and might well be carried a step farther. A diagnosis of late latent syphilis may be correct as far as it is possible to determine, and yet the patient may have a concealed active lesion. Thus, it is equally appropriate to give a latent case the chemotherapy preceding penicillin.

There is fairly general agreement that late latent syphilis is a field in which penicillin treatment is far from proved in value.⁷⁶⁻⁹¹⁻⁹³ It is not yet known whether penicillin may be of preventive value in latent syphilis, although the efficacy of traditional chemotherapy has long been accepted in that respect. It will take many years to determine this point. Certainly, one should not rely on penicillin alone in either latent or active late syphilis until far more has been accomplished with this mode of treatment. The suggested dosage schedules in many cases are similar to those recommended for neurosyphilis.

In late cutaneous syphilis moderate doses of penicillin have been striking in their effect.⁷⁶ Not all late gummatous syphilis is responsive to penicillin.⁹⁴ Syphilis of the bone is known to respond satisfactorily to penicillin therapy in most cases.⁷⁶⁻⁹⁵ A word of caution should be interjected regarding these so-called benign forms of late syphilis. Their clinical response to any form of therapy may seem satisfactory, but serologic response is often exceedingly slow and sometimes apparently nonexistent. It must be constantly borne in mind that syphilis is a systemic disease and reliance cannot be placed upon the behavior of any one symptomatic phase of the disorder.

A survey of 550 patients with late syphilis treated by penicillin has appeared from the Johns Hopkins

Hospital and casts a decidedly questionable light on the value of this treatment.⁹¹ Treatment failures are said to occur in the form of drug resistance, clinical progression, recurrence of lesions after an initially favorable response and the subsequent development of new manifestations of syphilis elsewhere in the body. A significant number of cases are presented, suggesting that penicillin may prove less efficacious in the later stages of syphilitic infection than during the more acute early phases of the disease. It is obvious that a great deal of further observation is required before penicillin may be considered lastingly efficacious in late syphilis. Perhaps this agent should be regarded as an adjuvant to traditional chemotherapy in some forms of late syphilis, rather than vice versa as considered in early stages of the disease.

CARDIOVASCULAR SYPHILIS

Several general reviews of the problem of cardiovascular syphilis and additional studies of special phases have been reported during the past year.

It is estimated that 10 per cent of all cases of early syphilis develop cardiovascular involvement.⁹² This should be preventable by adequate therapy early in the disease. A survey of 177 cases of cardiovascular syphilis was undertaken to determine how many patients had received adequate treatment either during the early stages of their syphilis or during the latent period, and to determine the effect of treatment on advanced cases of syphilitic aortitis.⁹³ Exceedingly low percentages of all the types of cardiovascular syphilis were found to have had anything like adequate treatment in the early stages of the disease. Some of these patients were under observation for ten years or more. The authors were unable to determine definitely what effect, if any, specific antisyphilitic treatment had had upon prolonging the life of these patients. It was stated that treatment of uncomplicated syphilitic aortitis will often prevent the development of serious cardiovascular complications. Once aortic insufficiency or aneurysm has developed, it is questionable whether antisyphilitic treatment can arrest the process, and it must certainly be used with great caution. One reviewer states that syphilis of the aorta and its complications comprise 13 to 15 per cent of all cardiac diseases found at autopsy.⁹⁴ Another presentation discusses a study of 43 patients with syphilitic aortic insufficiency who had received standard chemotherapy and were followed from two to sixteen years.⁹⁵ The data indicated that there may be an asymptomatic phase of from two to ten years followed by a symptomatic period, which may last an additional two to fourteen years. Cardiac failure was found to be as readily controlled with digitalis and mercurial diuretics as in other types of heart disease. An analysis of 59 cases of aortic aneurysm is also available.⁹⁶ Only 25 per cent of these patients gave a history of a

chancre. None were considered to have received adequate treatment. No difference was found in the appearance of the lesion in treated and untreated cases.

Therapy

All writers on this topic are in agreement that in the presence of cardiovascular syphilis, patients should be prepared with bismuth injections to prevent Herxheimer reactions.^{71 71 97 100} Individualization of the patient is imperative. Cardiac therapy should be the same as that for heart disease from other causes. Antisyphilitic therapy should be stopped if the patient is not improving or is growing worse, and treatment should be directed to the heart condition until cardiac signs and symptoms improve. Antisyphilitic therapy should invariably be withheld in the presence of cardiac failure. In the early days of penicillin there was considerable hesitance on the part of cardiologists to use this antibiotic in the treatment of cardiovascular syphilis. Experience has proved penicillin less dangerous to these patients than was at first believed. Initial doses as low as a few hundred units are advocated. One series comprised 28 patients with syphilitic aortic insufficiency and 8 with thoracic aortic aneurysm.¹⁰¹ Total dosage varied from 2,000,000 to 15,000,000 units, and there was an absence of severe reactions throughout. Five patients had fever within the first sixteen hours of treatment, and 2 with long-standing angina at rest had attacks of usual severity and frequency during and subsequent to administration of penicillin. In no case was the treatment schedule interrupted. There was no significant difference in the incidence of reactions or cardiovascular symptoms in the patients who received small initial doses as compared with those who received 25,000 to 100,000 units for their first dose. The average total of penicillin therapy advocated has been 6,000,000 units in from ten to fifteen days.^{71 99}

One author states that there is too little knowledge regarding the treatment of cardiovascular syphilis with penicillin for this subject to be discussed intelligently.⁹⁷ He believes that the weight of evidence indicates that syphilitic aortitis will not be permanently arrested unless arsenical therapy is included in any course of thorough and prolonged treatment. The arsenical agent of choice is stated to be arsenoxide (mapharsen, chlorarsen or similar preparations). It remains to be seen whether this opinion is correct as further work with penicillin progresses. It may well be ten to twenty years before the question of penicillin therapy in complicated syphilitic aortitis can be settled.

NEUROSYPHILIS

Next to early syphilis, more effort has been expended in the study of penicillin therapy of neurosyphilis than any other phase of the disease.

Results with penicillin have not been so dramatic as in early syphilis. The most outstanding effect has been favorable changes in the spinal fluid, particularly the cell count. There is considerable controversy regarding the question of using penicillin alone versus penicillin combined with fever therapy or other adjuvants in the treatment of neurosyphilis.

One of the most easily recognized objective findings in neurosyphilis and one upon which much reliance is placed is inequality of the pupils. The incidence of anisocoria was found to be nearly 17 per cent in a study of 500 normal subjects¹⁰². In $\frac{1}{4}$ per cent of this group there was a pronounced difference in pupillary size. Inequality of the palpebral fissures was even more frequent. Imbalance of sympathetic innervation and differences in refractive errors are considered to be possible explanations for at least some cases of anisocoria. It is obvious that too much reliance cannot be placed upon this one objective finding in an attempt to establish a diagnosis of neurosyphilis.

In a study of 54 patients with syphilitic primary optic atrophy, it was found that loss of vision was the first manifestation of neurosyphilis in 63 per cent¹⁰³. The optic atrophy was generally found to be accompanied by strongly positive cerebrospinal-fluid findings unless antisyphilitic treatment had been started. A majority of the cases exhibited the tabetic type of neurosyphilis. Fever therapy was found to be superior to chemotherapy in this series and the prognosis was not too unfavorable, provided that treatment was begun before useful vision had been lost. Of 16 patients given fever therapy in addition to chemotherapy, only 2 (13 per cent) were blind on follow-up examination two years or more after treatment. Another study led to the advocacy of malarial therapy aided by concomitant and subsequent courses of penicillin, each course consisting of the administration of at least 5,000,000 units¹⁰⁴. This work comprised a study of anatomic material of 12 cases of syphilitic primary optic atrophy, in 2 of which death had occurred at a time when the atrophy was confined to one eye. It was found that by the time demyelination of the nerve fibers had progressed to complete degeneration in one optic nerve, there was already present in the normal nerve a syphilitic inflammatory exudate that ultimately led to atrophy of the second nerve. It was stated that optochiasmatic arachnoiditis has nothing to do with the atrophy of the optic nerves.

In nerve deafness due to syphilis, penicillin has been found to be fully as effective as the older methods of therapy, only 13 patients with syphilitic deafness were studied, but this complication is not a common one¹⁰⁵. Patients with acute syphilitic meningitis and deafness responded rather well. In late syphilis with deafness of longer duration, the response to penicillin therapy was less favorable and considerably delayed. Some patients showed

no improvement, but there was no progression. One case of late congenital syphilis continued to show progressive loss of hearing. There was no evidence that penicillin has an unfavorable effect on hearing.

In severe, poorly regulated diabetes mellitus of long duration there may be neurologic changes that closely mimic tabes dorsalis (diabetic pseudotabes). Sensory disturbances, evidences of posterior-column damage, areflexia and a predilection for the lower extremities are common to both conditions. A group of 17 cases of neuropathic arthropathy of the feet associated with diabetes mellitus has been reported¹⁰⁶. These patients had destruction of the tarsal or metatarsal bones that was roentgenologically similar to that observed in Charcot joints. It was pointed out that the Charcot joint is more likely to exhibit an acute onset of fluid with swelling of the extremity and is usually painful during the acute stage and that new bone formation can frequently be demonstrated in the Charcot joint, whereas these findings are seldom notable in the diabetic neuropathic foot. The Charcot joint is relatively less frequent in the foot than in other joints, whereas feet are the most common site of diabetic neuropathy. Two additional cases have been reported in which neurogenic arthropathy of the Charcot type in severe diabetes of long standing was accompanied by the development of cord bladder¹⁰⁷. Here again are examples of the occurrence of lesions commonly designated as evidence of neurosyphilis in nonsyphilitic persons. Nevertheless, it is necessary to exert every effort to rule out neurosyphilis, regardless of negative serologic tests for syphilis, by careful clinical examination and lumbar puncture in patients such as those described. In other words, diabetic neuropathy should not be allowed to mask an actual case of neurosyphilis.

There is general agreement among syphilologists that spinal-fluid findings are of primary import in the diagnosis and management of neurosyphilis. It is not agreed, however, what constitutes normal standards for some of the tests done on the spinal fluid or what the different tests signify. There are four that should certainly be considered obligatory in all cases: cell count, total protein, colloidal gold and complement-fixation test. No single item will give complete information on the process involving the central-nervous system. An evaluation of spinal-fluid tests, based on thousands of examinations, has appeared from Bellevue Hospital¹⁰⁸. The presence of 3 cells per cubic millimeter of spinal fluid is regarded as normal, 3 to 5 cells are considered to represent borderline values, and more than 5 cells are held to be definitely pathologic. The cell count should be a reliable indication of the activity of the process. The total protein determination in association with the cell count is a further indication of activity, normal values for total protein in the spinal fluid are stated to range from 10 to 30 mg

per 100 cc. The colloidal gold test in its qualitative aspect gives a clue to the prevalent type of central-nervous-system tissue involvement, and its quantitative values offer an indication of the trend of the process. It is stated that in addition to a qualitative trend, a quantitative value may be obtained by addition of the ten figures of the colloidal gold test, a comparison of results is afforded with spinal fluids examined at various periods in the follow-up study of treated patients. The complement-fixation test should signify the specific nature of the syphilitic disease. Quantitative reagin readings, together with the other tests, provide additional information about whether the process in the central nervous system is progressing or abating or has been checked and thereby permit more intelligent management of a patient with neurosyphilis. Quantitatively determined spinal-fluid examinations have not been in general usage, but their value is being more widely recognized.¹⁰⁹

Therapy with Penicillin Alone

Stokes and his associates¹¹⁰ have presented a three-year study of penicillin alone in the treatment of neurosyphilis at the University of Pennsylvania, 361 patients were followed for periods of three months to three years. Of the total number of patients followed, spinal fluids were normal or nearly normal in over half, 74 per cent were markedly improved. Improvement in the spinal fluid appeared to level off in approximately 70 per cent of cases by the second year. Additional courses of penicillin produced little further improvement in most cases. In symptomatic neurosyphilis a single course of 9,600,000 units in aqueous solution given at two-hour intervals during a period of ten to fifteen days is under study. Asymptomatic neurosyphilis is being treated with penicillin in oil and wax. A comparison of the results of penicillin therapy and malaria suggested that penicillin alone is equal to or better than malaria in the management of neurosyphilis. In *tabes dorsalis*, the results with penicillin were considered to be twice as good after the second year as with malaria. Low initial doses (500 units) of penicillin, increasing to full dosage by the fifth day, were stressed to avoid therapeutic shock. A still greater percentage of satisfactory results is reported in the treatment of neurosyphilis with penicillin alone at Bellevue Hospital.¹¹¹⁻¹¹⁴ The total dose varied from 2,000,000 to 9,000,000 units, and the injections varied from 75 to 200. There were 301 patients with active neurosyphilis who were treated and followed from six to forty-five months, of which only 11 per cent had to be retreated. Of the original failures over half responded well to a second treatment with larger total doses of penicillin alone. The evaluation of therapy in this group of patients was based almost entirely on the results of repeated spinal-fluid examinations.

Another series of 141 patients received 4,000,000 units of penicillin, and the neurosyphilitic process was considered arrested in approximately 85 per cent of the cases.¹¹⁵ Early neurosyphilis responded more satisfactorily, and in cases of this type the results were as good as those obtained from fever therapy. It was concluded that in late symptomatic neurosyphilis, fever therapy was the treatment of choice. A schedule of 6,000,000 units of aqueous penicillin in eighteen days is considered satisfactory by another author.⁷⁴ He believes that at least 90 per cent of neurosyphilis will be arrested by that amount of penicillin and states that 9,000,000 to 12,000,000 units of penicillin in oil and wax over a period of eighteen to twenty days will probably give comparable results.

To evaluate the effect of previous chemotherapy on the results of penicillin treatment of neurosyphilis, clinical and serologic observations were made in 45 patients followed for one or two years after subsequent penicillin treatment.¹¹⁶ Total dosages of 8,000,000 to 12,000,000 units were given for eighteen to twenty-one days. Penicillin was considered superior or equal to malaria in the treatment of all phases of neurosyphilis with the possible exception of paresis. Mixed opinions regarding the use of penicillin alone versus penicillin and malaria in the treatment of neurosyphilis are expressed by other authors.¹¹⁷⁻¹¹⁹ It is indicated in general that the more advanced and serious forms of neurosyphilis often require repeated courses of penicillin or penicillin and fever combinations to achieve success.

An analysis of the blood serologic tests in 213 cases of late symptomatic neurosyphilis treated with various amounts of penicillin and observed for periods of six to twenty-four months or more after treatment indicated that less than 10 per cent of the patients attained complete serologic reversal.¹²⁰ Increased penicillin dosage or repetition of the course did not increase the percentage of serologic reversal. These findings are in agreement with the generally observed fact that penicillin seems to have little effect in reversing the positive blood serologic tests to negative in late neurosyphilis.

Intrathecal administration of penicillin has been advocated from a few sources but has not received general approval. One series of 179 cases has been reported, but the results are not superior to those in most of the aforementioned penicillin schedules with intramuscular injection.¹²¹ Reactions to intrathecal penicillin were stated to be about the same as those following routine lumbar puncture and less than those following Swift-Ellis treatments or malaria. Serious toxic effects have also been reported, however, and there is certainly little or no evidence that intrathecal administration is of greater therapeutic value in neurosyphilis than intramuscular injections.^{119, 122}

Combination Therapy

A number of authors reporting studies of varied methods of therapy of neurosyphilis state that the combination of penicillin and fever therapy is the treatment of choice in neurosyphilis, especially in the later symptomatic varieties.^{71 76 123} Assorted doses of from 4,000,000 to 20,000,000 units of penicillin are advocated in accordance with the type of neurosyphilis under consideration. Several methods of inducing fever have been employed, but malaria seems to be in more general use. There appears to be no striking difference in results whether the fever and penicillin are given concurrently or successively.

One study surveys progress as measured by the spinal-fluid examination among 458 cases of neurosyphilis treated with mechanical hyperthermy, malaria or penicillin in oil and wax with adjuvant chemotherapy.¹²⁴ All cases included in this group had a minimum observation period of six months. On the basis of failure rates, there were no significant differences among the three types of treatment in any diagnostic group. Penicillin appeared to eliminate activity in the spinal fluid more rapidly than the hyperthermy or malaria treatment. It should be remembered that this was not penicillin alone but with added chemotherapy. Various combinations of penicillin with fever or chemotherapy, or both, according to the type of neurosyphilis, are advocated elsewhere.¹¹⁹

A report from the Johns Hopkins Hospital on the treatment of 149 patients with neurosyphilis with penicillin alone or penicillin and malaria indicated that the patients in the latter group exhibited a more striking spinal-fluid response than those treated with penicillin alone.¹²⁵ The majority of patients had advanced neurosyphilis with pronounced spinal-fluid changes. Another series of 118 cases of neurosyphilis was managed in a similar fashion.¹²⁶ The combined penicillin and malaria therapy was generally administered to patients presenting the more serious clinical picture. The results for all types of central-nervous-system syphilis showed a distinctly superior clinical and spinal-fluid improvement after therapy in the patients given penicillin in combination with malaria as compared with those treated with penicillin alone.

The admittedly greater hazard of fever therapy, regardless of the method of induction, should largely discount its apparently somewhat greater value except in the more advanced and serious forms of neurosyphilis. Many patients in this category are so debilitated that fever therapy is out of the question and malaria therapy in particular has certain special contraindications. It is ardently hoped that improved methods of administration of penicillin will bring forth more evidence of its greater effectiveness in neurosyphilis.

Malaria therapy also presents a greater possibility of complications, studies in two series of neurosyphilitic patients gave laboratory evidence of impaired liver function in all or most of the patients.^{127 128} The degree of hepatomegaly could not be correlated with the severity of liver dysfunction. After termination of the malarial fever, most abnormalities gradually returned to normal. In no case was there evidence of permanent liver damage. Attention has again been called to the efficacy of thiobismol (sodium bismuth glycollate) in reducing the frequency of vivax malaria paroxysms without eliminating them completely.¹²⁹ This drug exerts an inhibitory effect upon half-grown parasites and thus facilitates temporary interruptions of malaria that may permit a full course of therapy without rapidly exhausting a patient who may be having daily febrile episodes. In quartan malaria, the use of thiobismol is less well understood, but it seems to be effective.

It is obvious that penicillin has a definite and established place in the treatment of neurosyphilis. Whether this antibiotic will prove sufficient by itself is yet to be determined. There is certainly evidence that in the more advanced forms of neurosyphilis, the combination of penicillin with fever and possibly with chemotherapy has a place. As stressed above, the preparation of patients with late syphilis with a series of bismuth treatments before any more dramatic form of therapy is given is an intelligent procedure. Neurosyphilis in its entirety falls within this category.

SYPHILIS IN PREGNANCY

The primary purpose of laws requiring a prenatal serologic test for syphilis is the protection of unborn children. Evaluation of these measures must therefore be in terms of the incidence of congenital syphilis. Many states have enacted such legislation, and a survey of the effectiveness of the law in 1 case was recently reported.¹³⁰ In a six-year period during the operation of this law, the population of the state showed a 34 per cent increase with a corresponding increase in the number of births, but the infant mortality for syphilis decreased from 0.50 to 0.15 per thousand live births. During the same interval the number of patients with congenital syphilis under one year of age reported to the state department of public health dropped from 163 to 74. This is a decrease in case rate from 1.60 to 0.54 per thousand live births. As reflected in these percentages, the effectiveness of the prenatal blood-test law is obvious.

The use of penicillin therapy for syphilis in pregnancy has been studied to a moderate extent, and the results appear most encouraging. A group of 287 cases of syphilis in pregnancy treated with penicillin has been reported from Bellevue Hospital.¹³¹ Among the patients treated only during pregnancy, there was an incidence of 2.8 per cent

per 100 cc. The colloidal gold test in its qualitative aspect gives a clue to the prevalent type of central-nervous-system tissue involvement, and its quantitative values offer an indication of the trend of the process. It is stated that in addition to a qualitative trend, a quantitative value may be obtained by addition of the ten figures of the colloidal gold test, a comparison of results is afforded with spinal fluids examined at various periods in the follow-up study of treated patients. The complement-fixation test should signify the specific nature of the syphilitic disease. Quantitative reagin readings, together with the other tests, provide additional information about whether the process in the central nervous system is progressing or abating or has been checked and thereby permit more intelligent management of a patient with neurosyphilis. Quantitatively determined spinal-fluid examinations have not been in general usage, but their value is being more widely recognized.¹⁰⁹

Therapy with Penicillin Alone

Stokes and his associates¹¹⁰ have presented a three-year study of penicillin alone in the treatment of neurosyphilis at the University of Pennsylvania, 361 patients were followed for periods of three months to three years. Of the total number of patients followed, spinal fluids were normal or nearly normal in over half, 74 per cent were markedly improved. Improvement in the spinal fluid appeared to level off in approximately 70 per cent of cases by the second year. Additional courses of penicillin produced little further improvement in most cases. In symptomatic neurosyphilis a single course of 9,600,000 units in aqueous solution given at two-hour intervals during a period of ten to fifteen days is under study. Asymptomatic neurosyphilis is being treated with penicillin in oil and wax. A comparison of the results of penicillin therapy and malaria suggested that penicillin alone is equal to or better than malaria in the management of neurosyphilis. In *tabes dorsalis*, the results with penicillin were considered to be twice as good after the second year as with malaria. Low initial doses (500 units) of penicillin, increasing to full dosage by the fifth day, were stressed to avoid therapeutic shock. A still greater percentage of satisfactory results is reported in the treatment of neurosyphilis with penicillin alone at Bellevue Hospital.¹¹¹⁻¹¹⁴ The total dose varied from 2,000,000 to 9,000,000 units, and the injections varied from 75 to 200. There were 301 patients with active neurosyphilis who were treated and followed from six to forty-five months, of which only 11 per cent had to be retreated. Of the original failures over half responded well to a second treatment with larger total doses of penicillin alone. The evaluation of therapy in this group of patients was based almost entirely on the results of repeated spinal-fluid examinations.

Another series of 141 patients received 4,000,000 units of penicillin, and the neurosyphilitic process was considered arrested in approximately 85 per cent of the cases.¹¹⁵ Early neurosyphilis responded more satisfactorily, and in cases of this type the results were as good as those obtained from fever therapy. It was concluded that in late symptomatic neurosyphilis, fever therapy was the treatment of choice. A schedule of 6,000,000 units of aqueous penicillin in eighteen days is considered satisfactory by another author.⁷⁴ He believes that at least 90 per cent of neurosyphilis will be arrested by that amount of penicillin and states that 9,000,000 to 12,000,000 units of penicillin in oil and wax over a period of eighteen to twenty days will probably give comparable results.

To evaluate the effect of previous chemotherapy on the results of penicillin treatment of neurosyphilis, clinical and serologic observations were made in 45 patients followed for one or two years after subsequent penicillin treatment.¹¹⁶ Total dosages of 8,000,000 to 12,000,000 units were given for eighteen to twenty-one days. Penicillin was considered superior or equal to malaria in the treatment of all phases of neurosyphilis with the possible exception of paresis. Mixed opinions regarding the use of penicillin alone versus penicillin and malaria in the treatment of neurosyphilis are expressed by other authors.¹¹⁷⁻¹¹⁹ It is indicated in general that the more advanced and serious forms of neurosyphilis often require repeated courses of penicillin or penicillin and fever combinations to achieve success.

An analysis of the blood serologic tests in 213 cases of late symptomatic neurosyphilis treated with various amounts of penicillin and observed for periods of six to twenty-four months or more after treatment indicated that less than 10 per cent of the patients attained complete serologic reversal.¹²⁰ Increased penicillin dosage or repetition of the course did not increase the percentage of serologic reversal. These findings are in agreement with the generally observed fact that penicillin seems to have little effect in reversing the positive blood serologic tests to negative in late neurosyphilis.

Intrathecal administration of penicillin has been advocated from a few sources but has not received general approval. One series of 179 cases has been reported, but the results are not superior to those in most of the aforementioned penicillin schedules with intramuscular injection.¹²¹ Reactions to intrathecal penicillin were stated to be about the same as those following routine lumbar puncture and less than those following Swift-Ellis treatments or malaria. Serious toxic effects have also been reported, however, and there is certainly little or no evidence that intrathecal administration is of greater therapeutic value in neurosyphilis than intramuscular injections.^{119, 122}

A small number of patients will develop erythematous or erythematopapular eruptions within the first day or two after the beginning of penicillin therapy. These are usually mild affairs, lasting but a few days, and do not require interruption of therapy. A slightly larger proportion of patients may have urticaria, which is more likely to occur about a week after the beginning of penicillin treatment but may appear as late as the tenth or twelfth day, and occasional cases of post-therapy urticarias have appeared from two to four weeks after completion of penicillin treatment. Infrequently, these will be severe with angioneurotic manifestations, erythema-nodosum-like eruptions, distressing arthralgias and fever. These more pronounced reactions may require a week or more to subside in spite of all therapy. In most of the urticarias the penicillin may be continued with the assistance of antihistaminic drugs. A still rarer complication is a vesicobullous or pemphigoid type of dermatitis, which can be violent and incapacitating. There is also occasionally observed a localized dermatitis at the site of injections of penicillin. These are ascribed by some to the subcutaneous deposition of the drug, but there is not general agreement on this point. These local reactions respond much better to the application of cold than to hot applications.

In a survey of the treatment of over 10,000 cases of syphilis with penicillin it was stated that no serious reactions were observed.¹³⁶ These authors likened the urticarial reactions to serum sickness. This phenomenon was observed in a few patients as long as two months after treatment had been completed. The incidence of erythematous and papular eruptions in this series was 0.25 per cent. Only 2 patients out of the 10,000 developed a bullous dermatitis, which was limited to the exposed surfaces of the upper extremities. Such a peculiar localization has not been generally characteristic of the bullous type of reaction and suggests the possibility of extraneous or secondary factors. Attention was called to the occurrence of exacerbations of secondary syphilitic lesions, which appeared from the sixth to the tenth day after the start of treatment. This gave the appearance of an actual relapse of secondary syphilis, but darkfield examination of serum from lesions was always negative. No additional treatment was given, and the lesions receded in four or five days. The patients in whom this occurred have had ultimate good therapeutic results from penicillin treatment. Such phenomena seemed to resemble a delayed Herxheimer reaction, although the authors state that the occurrence of a delayed Herxheimer reaction has not heretofore been observed.

It was pointed out in a study of cutaneous reactions to penicillin that patients whose skins are in an unstable equilibrium because of some exudative dermatosis may be poor risks with penicillin therapy

regardless of whether it is topically applied or injected.¹³⁷ Such persons might easily be those who would be more likely to become sensitized to the antibiotic. The fact that severe allergic reactions can occur is stressed in another publication.¹³⁸ In a series of 5000 patients treated with penicillin in an Army hospital, there were 6 reactions of such severity that it became necessary to discontinue the drug. Four were urticarial, occurring early in the course of treatment, 2 were delayed and simulated serum sickness. Preadministration testing for penicillin sensitivity was found to be neither reliable nor practicable.

In a comparison of the incidence of significant penicillin reactions, data were taken from several schemes of therapy as employed on a nationwide basis in many thousand patients.⁷⁰ The rate of reactions per thousand patients was as follows: aqueous solution of penicillin 6.3, penicillin in oil and beeswax 3.1, aqueous solution of penicillin with arsenoxide 15.9, penicillin in oil and beeswax with arsenoxide 7.6. There were 16 deaths among a total of 162,278 patients: 15 in patients treated with aqueous penicillin with arsenoxide, and 1 in a patient treated with penicillin in oil and beeswax with arsenoxide. This is immediate confirmation of the hazard of combined therapy using arsenic as adjuvant therapy to penicillin.

BAL

Although less and less arsenotherapy is being employed, there is considerable literature regarding the value of the relatively new detoxifying agent for metallic therapy known as BAL (2,3-dimercaptopropanol). That BAL has a suppressive action on the treponemicidal effect of the trivalent arsenical preparations has been demonstrated.¹³⁹ Five patients with acute early syphilis were treated with BAL and oxophenarsine hydrochloride concomitantly. The organisms (*Treponema pallidum*) were found by darkfield much longer than they would have been under efficient arsenotherapy. After the termination of the experiment these patients were given sufficient penicillin therapy, and each experienced a Herxheimer reaction equal to or greater than the initial one seen after the first injection of arsenic, which prompted the author to assume that many viable spirochetes were still present at the time penicillin therapy was started.

Unusually good response has been reported with the use of BAL in a series of 44 patients with severe and widespread arsenical dermatitis and that of the acute exfoliative type.¹⁴⁰ Thirty-one of these cases were benefited by treatment, and healing was obtained in an average of twenty-one days. The earliest sign of response was subsidence of the edema. The successful treatment with BAL of severe thrombopenic purpura after antisyphilitic arsenotherapy has been accomplished.¹⁴¹ There was complete recovery among 12 patients between the

of congenital syphilis. This figure dropped to 1.2 per cent in a group of women who had been treated from one to twenty months prior to pregnancy. Even this low figure might have been avoided except for unobserved serologic relapse in 1 uncooperative patient. The recommended dosage is 4,000,000 units of penicillin in twelve days. Patients should be examined at monthly intervals throughout the remainder of the pregnancy with quantitative serologic tests for syphilis to determine evidence of possible relapse and the necessity for retreatment. It is stated that retreatment during subsequent pregnancies is considered unnecessary, provided the patient is carefully observed. In another series of 81 infants born of penicillin-treated mothers with early infectious syphilis, only 1 stillbirth due to syphilis was encountered, and all the remaining infants were normal.¹³² This is a failure rate of 1.24 per cent. A comparable group of infants delivered of women who were treated by various methods of intensive arsenotherapy developed 10.7 per cent of congenital syphilis. That failure rate certainly indicates the superiority of penicillin therapy of the pregnant syphilitic woman. The authors present 2 case reports on mothers who produced infants free of syphilis despite the fact that they themselves showed mucocutaneous relapse after penicillin treatment.

A dose of 3,000,000 units of penicillin for syphilis in pregnancy is advocated from another source.⁷⁶ This amount of the drug was said to protect 95 per cent of the infants when given during the last part of the first trimester of pregnancy. It could be repeated in the third trimester if the mother's syphilis had not responded properly. Still another source recommends 4,000,000 units of aqueous solution of penicillin (every three hours, for 100 doses) with a protection rate of 95 per cent.⁷⁴ It is further stated that in all probability penicillin in beeswax and oil can be substituted for the aqueous solution, in the amount of 600,000 or 450,000 units daily for ten or fourteen days. These studies of the use of penicillin in syphilis of pregnancy tend to confirm earlier optimism.

One previous report of the use of massive arsenotherapy in early syphilis complicated by pregnancy exhibited a degree of success comparable to the best reported with penicillin.¹³³ The reactions to this treatment are excessive, and such hazards are unnecessary in the face of at least equally efficacious penicillin therapy without the dangers of chemotherapy. There seems little excuse for the continued use of arsenic in any pregnant woman with syphilis unless she is unable to tolerate penicillin in any form.

CONGENITAL SYPHILIS

Except in early congenital syphilis, the treatment of this phase of the disease has always been productive of less satisfactory results than most varieties of acquired syphilis. Penicillin has so far brought

about relatively little change in this situation. From the standpoint of the effect of penicillin on the serologic status of congenital syphilis, a series of 25 patients showed improvement in only 24 per cent of the cases.⁹³ Some authors have been most pessimistic about the effect of penicillin in congenital syphilis, one preferring the use of mapharsen and bismuth combined with fever therapy.⁷⁶

Congenital neurosyphilis has been considered one of the most adamant varieties and has not infrequently been recalcitrant to all types of therapy. A group of 11 patients with congenital paresis has been studied for comparison of penicillin with penicillin and malaria.¹¹⁷ Five received penicillin alone, and 6 were treated with the combined method. No significant difference was seen in clinical or spinal-fluid results.

Interstitial keratitis has always provided another complicated therapeutic problem. Klauder¹⁴⁴ reports a study of interstitial keratitis with particular reference to the results of penicillin therapy in a series of 72 patients. It was found that penicillin, like chemotherapy, does not prevent an initial attack of interstitial keratitis, involvement of the second eye, or recurrence of the disease in a previously affected eye. It was possible to evaluate results of treatment of 59 patients in terms of final visual acuity with refraction determined at intervals one to three years after therapy. The findings were compared with a similar group of 54 patients given adequate courses of fever and chemotherapy. There was no appreciable difference in the final visual acuity of the two groups. This lack of striking result in final visual acuity of penicillin-treated patients compared with older methods is consistent with clinical observations in which penicillin does not uniformly exert an immediately favorable effect on active interstitial keratitis. It has long been realized that antisymphilitic treatment is not ideal in the management of interstitial keratitis, but it does show results superior to those in untreated patients. Fever seems to be the most effective single form of therapy but should most certainly be supplemented by adjuvants. Penicillin should dispense with chemotherapy in this situation as in most other phases of syphilis. This opinion is supported by other observers.¹¹⁷

An efficient oral form of antisymphilitic therapy would be of great value for infected infants. There is a report of the use of penicillin dissolved in water and administered to normal uninfected infants at ages of one week to five months.¹³⁴ A dose of 25,000 units gave blood levels that were considered therapeutic for as long as three hours. Further pursuit of this work is surely warranted.

TREATMENT REACTIONS

Penicillin

One of the most remarkable benefits of penicillin has been its relative freedom from reactions, and yet no rose seems to be completely without thorns.

A small number of patients will develop erythematous or erythematopapular eruptions within the first day or two after the beginning of penicillin therapy. These are usually mild affairs, lasting but a few days, and do not require interruption of therapy. A slightly larger proportion of patients may have urticaria, which is more likely to occur about a week after the beginning of penicillin treatment but may appear as late as the tenth or twelfth day, and occasional cases of post-therapy urticaria have appeared from two to four weeks after completion of penicillin treatment. Infrequently, these will be severe with angioneurotic manifestations, erythema-nodosum-like eruptions, distressing arthralgias and fever. These more pronounced reactions may require a week or more to subside in spite of all therapy. In most of the urticarias the penicillin may be continued with the assistance of antihistaminic drugs. A still rarer complication is a vesicobullous or pemphigoid type of dermatitis, which can be violent and incapacitating. There is also occasionally observed a localized dermatitis at the site of injections of penicillin. These are ascribed by some to the subcutaneous deposition of the drug, but there is not general agreement on this point. These local reactions respond much better to the application of cold than to hot applications.

In a survey of the treatment of over 10,000 cases of syphilis with penicillin it was stated that no serious reactions were observed.¹³⁶ These authors likened the urticarial reactions to serum sickness. This phenomenon was observed in a few patients as long as two months after treatment had been completed. The incidence of erythematous and papular eruptions in this series was 0.25 per cent. Only 2 patients out of the 10,000 developed a bullous dermatitis, which was limited to the exposed surfaces of the upper extremities. Such a peculiar localization has not been generally characteristic of the bullous type of reaction and suggests the possibility of extraneous or secondary factors. Attention was called to the occurrence of exacerbations of secondary syphilitic lesions, which appeared from the sixth to the tenth day after the start of treatment. This gave the appearance of an actual relapse of secondary syphilis, but darkfield examination of serum from lesions was always negative. No additional treatment was given, and the lesions receded in four or five days. The patients in whom this occurred have had ultimate good therapeutic results from penicillin treatment. Such phenomena seemed to resemble a delayed Herxheimer reaction, although the authors state that the occurrence of a delayed Herxheimer reaction has not heretofore been observed.

It was pointed out in a study of cutaneous reactions to penicillin that patients whose skins are in an unstable equilibrium because of some exudative dermatosis may be poor risks with penicillin therapy

regardless of whether it is topically applied or injected.¹³⁷ Such persons might easily be those who would be more likely to become sensitized to the antibiotic. The fact that severe allergic reactions can occur is stressed in another publication.¹³⁸ In a series of 5000 patients treated with penicillin in an Army hospital, there were 6 reactions of such severity that it became necessary to discontinue the drug. Four were urticarial, occurring early in the course of treatment, 2 were delayed and simulated serum sickness. Preadministration testing for penicillin sensitivity was found to be neither reliable nor practicable.

In a comparison of the incidence of significant penicillin reactions, data were taken from several schemes of therapy as employed on a nationwide basis in many thousand patients.⁷⁰ The rate of reactions per thousand patients was as follows: aqueous solution of penicillin 6.3, penicillin in oil and beeswax 3.1, aqueous solution of penicillin with arsenoxide 15.9, penicillin in oil and beeswax with arsenoxide 7.6. There were 16 deaths among a total of 162,278 patients: 15 in patients treated with aqueous penicillin with arsenoxide, and 1 in a patient treated with penicillin in oil and beeswax with arsenoxide. This is immediate confirmation of the hazard of combined therapy using arsenic as adjuvant therapy to penicillin.

BAL

Although less and less arsenotherapy is being employed, there is considerable literature regarding the value of the relatively new detoxifying agent for metallic therapy known as BAL (2,3-dimercaptopropanol). That BAL has a suppressive action on the treponemicidal effect of the trivalent arsenical preparations has been demonstrated.¹³⁹ Five patients with acute early syphilis were treated with BAL and oxophenarsine hydrochloride concomitantly. The organisms (*Treponema pallidum*) were found by darkfield much longer than they would have been under efficient arsenotherapy. After the termination of the experiment these patients were given sufficient penicillin therapy, and each experienced a Herxheimer reaction equal to or greater than the initial one seen after the first injection of arsenic, which prompted the author to assume that many viable spirochetes were still present at the time penicillin therapy was started.

Unusually good response has been reported with the use of BAL in a series of 44 patients with severe and widespread arsenical dermatitis and that of the acute exfoliative type.¹⁴⁰ Thirty-one of these cases were benefited by treatment, and healing was obtained in an average of twenty-one days. The earliest sign of response was subsidence of the edema. The successful treatment with BAL of severe thrombopenic purpura after antisyphilitic arsenotherapy has been accomplished.¹⁴¹ There was complete recovery among 12 patients between the

ages of fifteen and thirty-nine years who had agranulocytosis incurred during arsenotherapy for syphilis and who were treated with BAL.¹⁴² The most dramatic results with the use of this drug have been observed in the sharp reduction of mortality in arsenical encephalitis.¹⁴³ To be effective the drug must be administered within a few hours after the onset of this complication. The dosage of BAL is 2.5 to 4 mg per kilogram of body weight. From four to six injections should be given daily for the first two days, with injections twice a day thereafter until recovery. BAL is considered a specific detoxifying agent for arsenic, mercury, gold and other heavy metals and is given intramuscularly. The antidotal action is considered due to its ability to remove the metal from combination with tissue proteins and the resultant excretion of a stable and relatively nontoxic substance. A review of the subject of postarsenical encephalopathy has recently appeared.¹⁴⁴ Two cases encountered before the days of BAL were described therein, with a description of post-mortem observations. This complication should fortunately be exceedingly rare hereafter with the steadily decreasing use of arsenotherapy.

The successful treatment of trypanosomiasis optic neuritis with BAL has been reported.¹⁴⁵ The usefulness of BAL in poisoning from metals other than arsenic is known. There is recorded another case of successful BAL therapy in gold intoxication.¹⁴⁶

The use of BAL is not unattended by reactions. Patients frequently complain of a tightness in the throat and an oppressive feeling in the retrosternal region. There may be burning of the lips, lacrimation, dryness of the mouth, nervousness and restlessness for periods of several minutes to an hour after treatment. Some patients experience considerable nausea and vomiting. Localized soreness and occasional abscess formation may be observed at the site of injection. The latter is particularly notable in patients with exfoliative dermatitis, as might be expected. Although no severe toxic reactions have thus far been reported, there is experimental evidence of enhanced toxicity of BAL in the presence of hepatic damage.¹⁴⁷ When BAL was injected into animals with severe renal impairment, no evidence of more toxic effects than those in normal animals was obtained.

Other experimental work indicates that thiamine in conjunction with BAL should exert a decidedly complementary effect in the treatment of arsenical toxicity.¹⁴⁸ A severe disturbance in carbohydrate metabolism during intensive arsenical therapy was noted during this experimentation.

SUMMARY

Despite a slight increase in infectious syphilis among the civilian population in the past year, the combined total of early disease among civilians and military personnel has shown a slight down-

ward trend. A ten-year survey of the deaths from syphilis revealed a most encouraging decrease. Control measures are being intensified throughout the country, with emphasis on public education, follow-up study of contacts and recognition of the role to be played by practicing physicians.

Improvement in the repository types of penicillin and wider employment of these products have facilitated the ambulatory treatment of syphilis and greatly reduced its cost to both patients and hospitals. It is surely the most practical approach and maintains adequate therapeutic levels with but one injection in twenty-four hours. For early syphilis, ten daily injections to total 6,000,000 units is the average recommendation, but more may often be advisable. There is continuous investigation of retardants to delay absorption and excretion of penicillin. Adjuvant therapy of assorted types is receiving further attention.

Penicillin G appears to cure about 90 per cent of early cases of syphilis among human beings, but it must be remembered that these patients have been so far followed for but a few years at most. The optimal therapy schedules have not yet been agreed upon, nor is there unanimity about methods of administration. The time-dose relation must be further clarified. Nevertheless, penicillin therapy of syphilis is obviously established by virtue of its shorter time requirement, relative simplicity and strikingly low rate of complications.

Neurosyphilis can apparently be arrested by penicillin in decidedly less time than by any other form of treatment, but adjuvant therapy may have a place in advanced cases. Other types of late or latent syphilis appear to be less favorably affected. All late cases of syphilis, symptomatic or latent, should receive bismuth therapy prior to penicillin to help guard against a therapeutic paradox.

Infection of the fetus will almost invariably be prevented or cured by adequate penicillin treatment of syphilis during pregnancy. Congenital infection is less responsive.

ages of fifteen and thirty-nine years who had agranulocytosis incurred during arsenotherapy for syphilis and who were treated with BAL.¹⁴² The most dramatic results with the use of this drug have been observed in the sharp reduction of mortality in arsenical encephalitis.¹⁴³ To be effective the drug must be administered within a few hours after the onset of this complication. The dosage of BAL is 2.5 to 4 mg per kilogram of body weight. From four to six injections should be given daily for the first two days, with injections twice a day thereafter until recovery. BAL is considered a specific detoxifying agent for arsenic, mercury, gold and other heavy metals and is given intramuscularly. The antidotal action is considered due to its ability to remove the metal from combination with tissue proteins and the resultant excretion of a stable and relatively nontoxic substance. A review of the subject of postarsenical encephalopathy has recently appeared.¹⁴⁴ Two cases encountered before the days of BAL were described therein, with a description of post-mortem observations. This complication should fortunately be exceedingly rare hereafter with the steadily decreasing use of arsenotherapy.

The successful treatment of trypanamide optic neuritis with BAL has been reported.¹⁴⁵ The usefulness of BAL in poisoning from metals other than arsenic is known. There is recorded another case of successful BAL therapy in gold intoxication.¹⁴⁶

The use of BAL is not unattended by reactions. Patients frequently complain of a tightness in the throat and an oppressive feeling in the retrosternal region. There may be burning of the lips, lacrimation, dryness of the mouth, nervousness and restlessness for periods of several minutes to an hour after treatment. Some patients experience considerable nausea and vomiting. Localized soreness and occasional abscess formation may be observed at the site of injection. The latter is particularly notable in patients with exfoliative dermatitis, as might be expected. Although no severe toxic reactions have thus far been reported, there is experimental evidence of enhanced toxicity of BAL in the presence of hepatic damage.¹⁴⁷ When BAL was injected into animals with severe renal impairment, no evidence of more toxic effects than those in normal animals was obtained.

Other experimental work indicates that thiamine in conjunction with BAL should exert a decidedly complementary effect in the treatment of arsenical toxicity.¹⁴⁸ A severe disturbance in carbohydrate metabolism during intensive arsenical therapy was noted during this experimentation.

SUMMARY

Despite a slight increase in infectious syphilis among the civilian population in the past year, the combined total of early disease among civilians and military personnel has shown a slight down-

ward trend. A ten-year survey of the deaths from syphilis revealed a most encouraging decrease. Control measures are being intensified throughout the country, with emphasis on public education, follow-up study of contacts and recognition of the role to be played by practicing physicians.

Improvement in the repository types of penicillin and wider employment of these products have facilitated the ambulatory treatment of syphilis and greatly reduced its cost to both patients and hospitals. It is surely the most practical approach and maintains adequate therapeutic levels with but one injection in twenty-four hours. For early syphilis, ten daily injections to total 6,000,000 units is the average recommendation, but more may often be advisable. There is continuous investigation of retardants to delay absorption and excretion of penicillin. Adjuvant therapy of assorted types is receiving further attention.

Penicillin G appears to cure about 90 per cent of early cases of syphilis among human beings, but it must be remembered that these patients have been so far followed for but a few years at most. The optimal therapy schedules have not yet been agreed upon, nor is there unanimity about methods of administration. The time-dose relation must be further clarified. Nevertheless, penicillin therapy of syphilis is obviously established by virtue of its shorter time requirement, relative simplicity and strikingly low rate of complications.

Neurosyphilis can apparently be arrested by penicillin in decidedly less time than by any other form of treatment, but adjuvant therapy may have a place in advanced cases. Other types of late or latent syphilis appear to be less favorably affected. All late cases of syphilis, symptomatic or latent, should receive bismuth therapy prior to penicillin to help guard against a therapeutic paradox.

Infection of the fetus will almost invariably be prevented or cured by adequate penicillin treatment of syphilis during pregnancy. Congenital infection is less responsive.

CASE 35111

PRESENTATION OF CASE

A one-year-old male child was referred to the hospital from a well-baby clinic, where an abdominal mass had been discovered.

The patient was the younger of two living children, and no irregularities were detected regard-

less. No lymph nodes were palpable. A prominence of the entire left abdomen was obvious by inspection, and many veins were visible over the abdomen. These were not engorged or tortuous. On palpation the mass was described as being firm, smooth and extending from beneath the left costal margin to the pelvic floor. A small notch was palpable on its medial surface at the level of the umbilicus, the lateral edge was not definitely palpable. There was no evident descent of this mass on inspiration. The liver and right kidney were not palpable. Examination of the chest was essentially negative.

The temperature was 100.2°F, the pulse 110, and the respirations 20-26. The blood pressure was 90 systolic, 50 diastolic.

Laboratory examination revealed a white-cell count of 9300, with 30 per cent neutrophils, 64 per cent lymphocytes, 4 per cent monocytes and 1 per cent eosinophils. The hemoglobin was 9.9 gm. The red blood cells showed some hypochromia and anisocytosis. The platelets appeared normal. The urine had a pH of 5.0 with a specific gravity of 1.022. The sediment showed 1 or 2 white blood cells per high-power field and amorphous crystals. The nonprotein nitrogen was 30 mg per 100 cc. Nose and throat cultures revealed a few alpha-hemolytic streptococci and *Staphylococcus albus*. A tuberculin test was negative in a dilution of 1:1000. X-ray examinations of the chest, skull and thoracolumbar spine showed no evidence of intrinsic disease. A plain film of the abdomen disclosed a large, oval tumor mass on the left, extending partially across the midline. This could not be separated from the shadow of the left kidney (Fig 1). There was no visible evidence of bone erosion or calcification within the mass. Intravenous dye was excreted slowly on the left, showing marked dilatation and upward displacement of the calyces and pelvis. Excretion on the right appeared within normal limits (Fig 2).

Operation was delayed because of an upper respiratory infection. However, on the tenth hospital day, following transfusion and preoperative doses of penicillin and streptomycin, an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR THOMAS H LANMAN* A painless mass in the left upper abdomen in a one-year-old child brings to mind right off some form of malignant lesion. But before considering cancer in detail we might go through the history, which has some significant points.

The prominence of the abdomen fits in with the tentative diagnosis I have in mind, and the appearance of the veins is interesting but not diagnostic.

The mass is described as firm. I judge it extended into the renal fossa but not into the pelvis. The

*Surgeon, Children's Hospital, Boston.

FIGURE 1

ing his birth, feeding or development. Within the two months preceding admission the mother had noticed a firm and painless mass in the child's left flank. He had had constipation, usually relieved by prunes and bran, most of his life, but the mother denied noticing any hematuria.

Physical examination revealed a well developed and well nourished, alert child in no apparent dis-

notch makes one consider the spleen, but as we shall see later it was probably not the spleen. The mass did not descend on inspiration, indicating that it was fairly well fixed. The right kidney was not palpable. The white-cell count showed only a relatively high percentage of lymphocytes, and I do not believe this is significant. There was slight anemia but nothing else abnormal in the blood examination, which is of some significance in excluding certain possibilities such as splenic enlargement.

The finding of streptococci in the nose and throat cultures was probably incidental.

The negative tuberculin test may be significant in some cases but does not enter into this differential diagnosis.

In summary, we have a firm mass that had pushed the intestines over toward the midline. The intravenous pyelogram shows distortion of the kidney pelvis and calyces. Here is a homogeneous mass pushing the bowel over to the opposite side, filling almost the entire abdomen on that side, and possibly extending to the midline but not beyond it. A solid tumor, especially in this age group, should be regarded as malignant until proved otherwise. I do not see anything in the history or in the blood examination to suggest disease of the spleen. The only thing here that might make one think of the spleen is the mention of a notch in the mass. There is nothing to suggest an enlarged spleen caused by either purpura or Banti's syndrome, nor is there anything to suggest hemolytic icterus. One would not expect a spleen of this size at this age without other symptoms of splenic disorder.

What other masses may there be? There are certain benign cysts, and the duplications of the intestinal tract. Cysts of the mesentery are, as a rule, not at all firm. They may attain a size as great as this but would be almost sure, even at this age, to give some gastrointestinal symptoms such as subacute obstruction, vomiting or loss of weight.

A duplication is usually cystic on palpation, but it may feel solid as this did, although it is extraordinarily rare for it to be both large and solid. If attached to the stomach or the bowel and of this size, I believe it certainly would have given something in the way of pressure symptoms and gastrointestinal symptoms.

With a hydronephrosis an enormous mass can occur, but the intravenous pyelogram would not show the abnormality of the pelvis, which we see here. This film shows displacement and compression of the calyces rather than dilatation from a congenital obstructive lesion causing a hydronephrosis in that kidney.

We come now to the types of malignant tumor usual in this age group and in this region. There are two—the embryoma, or Wilms tumor, and the neuroblastoma. In differentiating these two one

can sometimes make a good preoperative guess, although not always. Such a case is a good illustration of when the treatment is surgical, and the mass should be explored.

In addition to the Wilms tumor and neuroblastoma there are rare conditions that one must consider. The true hypernephroma, or Grawitz tumor, we have never encountered in this age. In addition to the Wilms tumor it is possible to have an embryoma arising retroperitoneally from the remains of the primitive mesonephron, which is

FIGURE 2

not attached to the kidney. These are hard to differentiate, but if one attained this size, this picture in the pyelogram, which suggests that the growth is in the kidney itself, would hardly be expected. In considering neuroblastoma, which is by far the commonest of the tumors of neurogenic origin, there are other tumors from the sympathetic system that one might perhaps encounter. Certainly the ganglioneuroma can be quite large, but such size is unusual as early as this.

Adrenal cortical tumors certainly would not attain this size without symptoms, characteristically they are small and, of course, give as outstanding symptoms changes in sex in the male, sex precocity, and in the female, a tendency to masculinization.

The Wilms tumor and neuroblastoma are about even in incidence in our series—93 of the former and 100 or more of the latter. There is not enough difference in numbers to be significant in differential diagnosis. A Wilms tumor usually occurs in early life—most of our cases between two and three

years of age, although we have seen the tumor in patients as young as two months. The neuroblastoma is likely to occur a little later. Three quarters of our cases of neuroblastoma have occurred at four or five years, although we have seen neuroblastoma as early as the seventh day of life. The physical examination perhaps gives a better differential than anything else—that is, the size, the shape and the feel of the mass. The Wilms tumor is smooth or somewhat lobulated, and I would imagine that the notch here was a lobule such as occurs in this type of tumor. A neuroblastoma is more likely to be nodular and rough. It is not always possible to differentiate. It is suggestive that the neuroblastoma usually does not attain such a size as soon as this. Very frequently in cases of neuroblastoma the attention of the mother or the physician may be focused upon the metastasis—that is, there may be evidence of metastasis before the tumor itself is found. Metastases may be seen in the lungs and bones of the skull, but they frequently appear in the long bones. In differentiating these two tumors it is sometimes valuable to take films of the long bones.

The absence of hematuria is not at all unusual. Hematuria is a rare symptom of a Wilms tumor, and certainly not more than a quarter of the patients have had hematuria as a presenting symptom. It is interesting to observe that in such cases the growth had broken through its capsule into the renal pelvis, and as a prognostic sign gross hematuria in a Wilms tumor is a very grave one; we have no case of cure when gross hematuria has been present preoperatively.

In this case from the history, the age and the described feeling of the mass and from the x-ray appearance, I shall make the diagnosis of a Wilms tumor.

DR TRACY B. MALLORY: Dr Wyman, would you like to comment on the films?

DR STANLEY M. WYMAN: I think there are perhaps one or two points to mention. The portions of the mass that one can see extending upward and laterally are extremely smooth in contour. The mass is homogeneous and shows no unusual calcification. The lateral view demonstrates the mass extending downward and extremely far anteriorly up to the abdominal wall. It does not appear to lie very far posteriorly. That is suggestive evidence, not conclusive, but the mass may lie more anteriorly than the kidney. Unfortunately, we do not have pyelogram films taken in an oblique position to determine this. There is a hint of a capsule on this mass, but it is not very definite, and I am not sure it is a valid finding. However, the whole picture raises an additional question in my mind: could this be a cystic lesion, possibly bowel duplication or mesenteric cyst, although it certainly does not sound that way from the physical examination? The large bowel seems to be displaced medial rather than lateral to it.

DR LANMAN: If that is a suggestion of capsule, it would fit in more with a Wilms tumor than with a neuroblastoma.

DR GERTRUD C. REYERSBACH: We wondered clinically about one thing. Was it not a very long interval? It was two months since the mother had discovered the mass, and was not the child apparently well?

DR LANMAN: I do not think that is particularly against a Wilms tumor. These growths go along quite locally and may go for some time. That is one of the most characteristic symptoms we have in our series—that the mother was the first to notice the tumor. The two-month interval here would not be against that diagnosis, though usually the mother seeks advice sooner.

DR J. GORDON SCANNELL: I think that there was universal agreement on the service with the differential diagnosis as given by Dr Lanman. We believed that we were dealing with a malignant tumor and that probably its vascular supply came from above and medially. We therefore elected to explore transthoracically and obtained excellent exposure of the vessels without disturbing the tumor itself. The renal vein was not very large and was divided first. Next the renal artery, as well as a few soft nodes which lay adjacent to it, was secured close to its source. The adrenal gland had previously been clearly visualized, was quite normal and was preserved. The tumor itself was a rather firm, oval mass without great vascularity. It obviously arose in the lower pole of the left kidney. With the vessels previously ligated, the kidney and its tumor were readily delivered and removed. About 15 or 20 cm. of ureter was removed with it.

DR BENJAMIN CASTLEMAN: Would you have given x-ray treatment preoperatively?

DR LANMAN: No.

CLINICAL DIAGNOSIS

Wilms tumor

DR LANMAN'S DIAGNOSIS

Wilms tumor

ANATOMICAL DIAGNOSIS

Cystic teratoma of kidney, benign

PATHOLOGICAL DISCUSSION

DR MALLORY: The tumor was a considerable surprise to all of us since it turned out to be cystic and looked, in fact, almost exactly similar to a multilocular ovarian cyst (Fig 3). One can see in the lantern slides that the lower two thirds of the kidney have been replaced by a multilocular cystic structure. Some of the cysts have thin and transparent walls, others are opaque. There were a few masses of solid tumor, and those that we found appeared to be fibrotic.

In microscopical sections from this tumor the cysts are lined by a very low, nonspecific-looking, cuboidal epithelium or possibly endothelium. The interstitial tissue consists almost entirely of fibrous tissue, most of which is well differentiated, although some is cellular in places and here and there, scattered through the tumor, are multiple, well differentiated, striated muscle fibers. These convince me that this was a teratoma that had differentiated in only two or three directions. We found nothing suggestive of teeth, hair, squamous epithelium and so forth, such as we sometimes find in teratomas. Teratoid tumors, of course, are found in the kidney and in the region of the kidney. Sometimes it is difficult to decide where they actually

per cent survival, from 1931-1939, 30 cases with 10 cures, a 33 per cent survival rate, from 1940-1947, 37 cases with 19 cures, a survival rate of 49 per cent. We regard a two-year postoperative interval with no symptoms of recurrence as a cure in this condition. But the most interesting feature in this study is that of these 93 cases, 63 per cent of the cures have been in patients one year old or younger, and in the last studied group, 1940-1947, 80 per cent of the cured patients among the 37 cases were younger than one year. In other words, it is in the early age group that prognosis appears to be best. Here is a condition that certainly justifies routine examination in the early months or years of life because these tumors frequently give no symptoms whatever until the mass is noted by the mother or by a physician. This present case is an extremely interesting type of tumor. I have never seen one like it.

FIGURE 3

arise. In this case there is no question that the tumor was intrarenal and was occupying the entire lower pole. I have never seen a tumor of this character, although I do not know whether in the material at the Children's Hospital you have.

DR LANMAN: No, we have not. What do you think about its degree of malignancy?

DR MALLORY: I think it was probably benign. We could find no foci typical enough to suggest malignancy. I would offer a good prognosis in this case.

DR LANMAN: I think it is an interesting case, and it is certainly new to me as a type of tumor in this region. The history is characteristic of embryoma. I think the treatment is the same in any case, and it brings out that exploration is the only way to decide what the tumors are. We are very much against the punch-biopsy type of diagnosis and are against preoperative radiation. I recently looked up our series of 93 cases of Wilms tumor from 1914-1947 and was encouraged to find that we have an over-all cure rate of 35 per cent. From 1914-1930 there were 26 cases with 4 cures, a 15

CASE 35112

PRESENTATION OF CASE

First admission. A twenty-six-year-old woman was admitted to the hospital because of hemoptysis.

Six years before admission the patient was suddenly seized with pain in the left lower chest. This was accompanied by fever and malaise. The fever and pain disappeared in the course of ten days. Two weeks later she developed a dry, hacking cough, which soon became productive. She did not return to work as a playground instructor for three months and shortly after this began coughing blood, about 7 cc daily, for four or five days. She had lost 20 pounds since the onset of the illness. The next three years were spent in bed, during which time a diagnosis of bronchiectasis of the left lower lobe was made. Treatment by weekly bronchoscopies and postural drainage cleared all the symptoms. She was perfectly well until six months before admission, when she had a repetition of the first illness. In spite of postural drainage and therapeutic bronchoscopies the bleeding continued.

Physical examination revealed dullness and flatness over the left base, decreased breath sounds and a few, fine rales. A chest x-ray was reported as follows:

There is a rounded, sharply defined, dense shadow lying in the costovertebral angle on the left side just above the diaphragm. This shadow measures about 2 cm in diameter and has very smooth, sharp borders. There is also generalized haziness in the lung field medial to the shadow. This shadow has the appearance of a foreign body. After injection of lipiodol there are numerous, dilated, clubbed bronchi in the lower lobe. The shadow previously described has the same density as lipiodol, probably representing a puddle of lipiodol from a previous injection.

A left phrenicectomy and left lower lobectomy were done. Except for phlebitis the convalescence was uneventful. On x-ray examination two months

later the stump of the main bronchus of the lower lobe appeared slightly widened and had some minor bronchi branching off in this region. These bronchi were surrounded by a soft-tissue mass, measuring about 5 cm in diameter, which may have represented the residue of the lower lobe.

Second admission (fourteen years later) Following discharge the symptoms all cleared except for hemoptysis, which occurred at intervals of six to

leaf of the diaphragm was elevated. There was thick pleura in the left base, this was probably the result of the previous operation. The left upper lobe and the right lung were clear. There was a slight shift of the mediastinum to the left (Fig 1 and 2).

On the second hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. JOHN W. STRIEDER* Whatever the cause of bleeding, which began some twenty years before entry, it was obviously not relieved by the left lower lobectomy, which was performed fourteen years before entry. It may therefore be assumed that the cause was not in that portion of the lobe removed at the time of lobectomy. I say "portion" advisedly because in that era tourniquet lobectomy

FIGURE 1

twelve months. The episodes were not associated with coughing. Six months before admission the patient noted increased frequency of hemoptysis and a sense of tightness beneath the lower sternum. This was associated with the taking on of extra household responsibilities. Usually the amount of blood varied between 30 and 90 cc. The episodes occurred mostly at night and every two or three weeks. There were no other symptoms.

The temperature was 99.2°F, and the pulse, respirations and blood pressure were normal.

There were dullness, decreased tactile fremitus, decreased bronchovesicular breath sounds and decreased spoken and whispered voice over the left posterior lung base. The hemoglobin was 12 gm, the white-cell count was 7900, with a normal differential. The urine was normal. An x-ray of the chest was reported as showing a rounded area of increased density, 5.5 cm in diameter, in the posterior portion of the left chest at the site of the previously resected left lower lobe. The upper margin of this soft-tissue shadow was adjacent to the intermediary bronchus on the left. The left

FIGURE 2

was the universal technic whereby pulmonary tissue was removed. For those who are not derived of that era, let me say that tourniquet lobectomy removed varying amounts of the lobe and left stumps of varying size, containing varying lengths of residual bronchi depending upon the site of amputation of the lobe. The pedicle was treated with hemostatic ligatures of catgut and, usually, pleuralized. In treating patients by modern operative technics a number of years after lower lobectomies by the tourniquet method, I have been impressed by the amount of pulmonary tissue that had been left

*Surgeon-in-chief for thoracic surgery Boston City Hospital

It has frequently been a source of wonder to me that the operation was so often successful to the degree that it was

At this point the exercise, therefore, resolves itself into a discussion on the basis of deduction to determine the source of bleeding. Was it in the left lower lobe, or was it in some other portion of the bronchopulmonary system? I think it is reasonable to assume on the basis of the record, there being no evidence to the contrary, that this patient's bleeding did come from the left lower lobe. So that it remains to determine what the nature of this lesion was that persisted in troubling this woman by repeated hemoptyses over a period of twenty years.

May we see the x-ray films?

DR STANLEY M. WYMAN: These films of the chest show the left leaf of the diaphragm to be elevated, with thickening of the superior border as a result of the old operation. The heart and mediastinum are displaced slightly toward the left. The overexposed grid film demonstrates a somewhat lobulated, homogeneous, sharply defined shadow in this region, which lies just about at the end of the stump of the left-lower-lobe bronchus. The shadow is seen in the lateral view to lie posteriorly, also in apposition with this major bronchus.

DR STRIEDER: Would you have any opinion about its density? Is it a solid tumor? Is it consistent with a cyst filled with fluid?

DR WYMAN: Unless the cyst contains fairly fatty material, I believe it would be the same density as a soft-tissue tumor. The suggestion of perhaps a little lobulation makes one wonder about the actual soft-tissue mass. There is a little irregularity of the contour. This is insufficient to allow me to say whether this is definitely a soft-tissue mass or a cyst, although I would lean toward the former.

DR STRIEDER: Are there flecks of calcium in it, or are these densities due to overlay?

DR WYMAN: I think it is overlying the shadow. The lung fields otherwise appear clear.

DR STRIEDER: So we have evidence of a round density, which, by comparison with the description of the films taken fourteen years previously, two months after operation, is similar in size, contour and density. The original films are not available, of course. The nature of the shadow described in the original films as being possibly a foreign body and then described as of the same density as the

lipiodol (and therefore suspected of being a residuum of a previous lipiodol injection) is a matter of conjecture. I think one cannot say more than that about it. That shadow was not present after the operation, so that whatever it was, it was apparently removed at the time of lobectomy.

Given an x-ray shadow that is suggestive of tumor within the thorax, any discussion as to the exact histopathology of the tumor resolves itself into a more or less philosophical exercise that, at best, is a poor substitute for the microscope once the specimen has been handed to the pathologist by the surgeon. The cogent question at the present is, What lesion that is familiar to me best satisfies the many facets of this history and would give all the end results described? To me, by all odds, the so-called bronchial adenoma best satisfies this history. Going back over the history, the onset suggests bronchial obstruction followed by atelectasis, with infection and the subsequent development of bronchiectasis. The patient had intermittent bleeding for twenty years in varying amounts. These occurred during the third and fourth decades in a woman who, at the onset, was nineteen or twenty and who, at the time of the last admission, was about forty. This also is consistent with so-called bronchial adenoma. She had a long course of bronchoscopies, and certainly during the course of these bronchoscopies it might well have been suggested that she had an obstructive lesion in the nature of an adenoma causing her difficulty. However, we have no information on that, and of course it is entirely possible that the tumor was beyond the range of vision of the bronchoscopist. But full cognizance was not taken of the obstruction or the compression that it might have caused. She came to operation, and a tourniquet lobectomy was performed. A small tumor, suitably located extrabronchially in relation to the intermediary bronchus, could have escaped inclusion in the amputated specimen. That is a possibility that we have to consider. We do not know what the specimen showed at the time of the original removal. If the lesion escaped, as I think we can assume it did, that is a satisfactory reason for her continuing to spit blood up to the time of her last admission. If it was an adenoma, the question comes up whether or not it had undergone malignant degeneration as these tumors are alleged to do by many competent observers. We have no

evidence from which I can deduce that it had undergone malignant degeneration, but I would say that the periodic hemoptoic episodes were against cancer. The malignant tumor that ulcerates tends to bleed day after day for periods in small amounts rather than to cause small, frank hemoptyses, which are consistent with adenoma.

Of course, other causes of bleeding should be considered. Tuberculosis is not suggested in any way by the films, the course or the laboratory data with which we are furnished. Other tumors that cause bleeding most commonly are the malignant tumors. Benign tumors, other than the so-called benign adenoma, are likely to cause bleeding on the basis of obstruction and infection. Again, we have no way of knowing whether she had obstruction with bronchiectasis and bleeding from it alone.

One other hypothetical possibility that appeals to me — it is hypothetical because I have not encountered it personally, nor have I seen it described in exactly this situation — is that the original episode was on the basis of infection and atelectasis and that she developed bronchiectasis without an obstructing lesion in the bronchus. In that case, she bled on the basis of bronchiectasis, and when the lobe was amputated by tourniquet lobectomy radicles were left from which she continued to bleed. To go farther, she may well have developed a bronchiectatic cyst by the same mechanism that we have seen bronchiectatic cysts develop in residual lobes unrecognized as having disease in them prior to the time of operation. Against this is the fact that she is not described as having sputum. We would expect her to have sputum unless there was complete isolation of the cyst from the main bronchial tree. There were no febrile episodes. I would think somewhere along the line she would have had a bout or two of fever, if a reservoir had developed. Finally, as described by the radiologist, the tumor appears solid rather than cystic, but this of course is relative. So although this possibility is attractive, I would discard it in favor of my first impression, and say that this patient had bronchial adenoma with the question of malignant degeneration.

CLINICAL DIAGNOSIS

Bronchial adenoma

DR STRIEDER'S DIAGNOSIS

Bronchial adenoma

ANATOMICAL DIAGNOSIS

Bronchial adenoma

PATHOLOGICAL DISCUSSION

DR TRACY B. MALLORY: At this point the aid of the bronchoscopist was sought. Will you tell us your findings, Dr. Benedict?

DR EDWARD B. BENEDICT: Bronchoscopy showed a small, round tumor about 1 cm. in diameter below the left-upper-lobe orifice, which bled rather easily. It was far enough below the orifice that I thought

FIGURE 3

simple resection of the stump of the bronchus could be performed.

DR J. GORDON SCANNELL: This patient was operated on by Dr. Edward D. Churchill on both occasions — in 1935 and again recently. As Dr. Strieder pointed out, a tourniquet lobectomy was done fourteen years previously. It is well recognized that a surprising amount of lower lobe may be left behind on such occasions. Apparently, there was no evidence at that time of an adenoma, and the procedure went uneventfully. At the second operation a tumor was obvious, lying in the region of the resected lobe, and this remnant was 4 or 5 cm.

in its three dimensions. It lay under the upper lobe, very much like a ball in a catcher's glove, and although endoscopically it might have been resected without sacrificing the upper lobe, surgically the blood vessels, arteries and veins to the upper lobe made it impossible to resect and preserve that lobe, and a pneumonectomy was therefore completed. That was done for technical reasons and not with the idea that this was a malignant tumor. There were no suspicious lymph nodes seen at operation.

DR MALLORY: I have a picture of the resected specimen (Fig 3). This is the upper lobe. I do not think that one can quite see the intrabronchial tumor. It was comparatively small, about 0.5 cm in diameter. External to that was this quite large mass, varying from 3 to 4 cm in diameter, lobular, quite firm and apparently well encapsulated. There were a number of regional lymph nodes, none of which appeared to show any involvement. Histologically this was a very characteristic bronchial adenoma of the type that closely resembles the carcinoids of the intestinal tract. The tumor consists of small bundles of epithelial cells anastomosing very widely with one another. The cells are uniform in size and character and occasionally in places in the tumor there is a suggestion of gland formation, but these are not true glands. They represent areas where the stroma has degenerated, leaving an apparently cyst-like space. These tumors are not infrequently invasive and do occasionally show metastases to regional lymph nodes and rarely show

distant metastases. In this case, in spite of twenty years' duration, it had not reached the lymph nodes.

DR ALFRED KRAVES: Did the original specimen show anything more than bronchiectasis?

DR MALLORY: That is all. The amputation had been below the level of the main bronchus. These tumors are often dumb-bell in shape, with a small nodule within the lumen of the bronchus and another nodule outside the wall. The external tumor is sometimes very much larger than the internal tumor, as it was in this case.

DR STRIEDER: I have not heard you state recently your impressions of the possibility of malignant degeneration of these tumors.

DR MALLORY: I have not seen any histologic evidence of a shift of the degree of malignancy. I think they are potentially of very low malignancy, and the ones that do invade and reach the regional lymph nodes do not look under the microscope any more malignant than the others. I think the situation is exactly analogous to the carcinoids of the intestinal tract, which can also be locally malignant and rarely produce distant metastases.

DR STRIEDER: You believe, then, that bronchiogenic carcinoma is never on the basis of such a precursor?

DR MALLORY: I do not believe there is any connection between them.

DR BENJAMIN CASTLEMAN: I believe we have had 40 or 50 cases of adenoma of the bronchus, and in only 1 was there a metastasis to a regional lymph node.

MEDICAL MANPOWER

IN THESE feverish days of reports, programs and proposals, a report has just appeared that is of vital interest to every thoughtful citizen and particularly to the physician, because its central theme is medical manpower. It is the so-called Voorhees report, the unanimous report to the Hoover Commission of the 11 medical and 5 lay members of the Committee on Federal Medical Services. This eighty-nine page document, supported by twelve detailed appendixes, is factual, unbiased and affirmative. It describes the magnitude of federal medical commitments, reveals administrative weaknesses and proposes drastic remedies. It is timely, because this country has reached the point where its bankruptcy in either money or manpower can

cost mankind that freedom for which it is desperately fighting throughout the world.

The United States gives varying degrees of (medical) care to 24,000,000 beneficiaries — about one-sixth of the nation. Four big and some forty smaller agencies of the government spent about one and one quarter billion dollars for health and medical services in fiscal year 1948, an increase of five times over 1940, and of 20 per cent even over 1947. In 1949, the V.A. alone will spend as much as all forty-six agencies did in 1948 — half of it for new hospitals. This enormous and expanding enterprise is devoid of any central plan.

The Government is competing against itself. Not only are federal hospitals being built alongside existing unused federal hospitals, but also they are being built in places where they cannot be staffed. "Nearly half of the 89 new V.A. hospitals are being built or planned in areas where experience has proven that it will be difficult, if not impossible, to secure adequate staffs." Construction is far out-running medical manpower. "In the V.A. alone, 5,600 beds are now closed because of inability to staff them." The armed-forces expansion program, on which peace is believed largely to depend, faces shipwreck on the rock of medical-manpower shortage, both quantitative and qualitative. In the race for manpower to serve a sixth of the nation the federal agencies are competing not only against one another but also against the five sixths now receiving federal aid under the recent Hill-Burton Act.

Unpalatable remedies are courageously and unanimously proposed by the Voorhees Committee. Waste must be eliminated, existing manpower must be efficiently used. Only by a unified system of federal hospitals can high-quality care in peace and national protection in war be achieved. Many federal hospitals, including Veterans Administration, Public Health Service and certain military general and even station hospitals at home, will be regrouped under a new nonmilitary Cabinet Department.

Our area surveys, which covered about one-sixth of the country's Federal hospital beds, showed that new construction costing over \$100,000,000 could probably be saved in these areas alone by such a plan. Except in war, if adequate care is to be given, specialists must be utilized in their home communities.

The armed forces, merged or unmerged, will retain military hospitals overseas and certain large

medical centers and certain small installations at home posts in remote districts, but unnecessary duplication will be avoided and supervision will be exercised by a deputy of the Secretary of Defense aided by an advisory committee including civilian doctors

There will be a unified medical supply system for all federal depots. Efforts to control and eliminate disease will be intensified. Medical research and training will cut across boundaries of service, department and government. The report ends

We have attempted to outline a method which we hope will correct the extravagance resulting from the present series of unrelated projects, and weld these together into an integrated, orderly whole. With such an organization, staffed with outstanding personnel, it should be possible to utilize our unequalled medical resources to the maximum, and by intelligent planning take steps which will make us a healthier and stronger nation

If these proposals sound Utopian it means that they are being viewed from a parochial or traditional position that no longer exists in hard reality. They must be considered in the light of a world situation, critical now, and bidding fair to remain so for years. No resting place has been reached on the climb toward security and freedom. The sacrifices ahead may be greater than those behind. Apathy is to be expected. Opposition is to be expected, both sincere and cynical. Understandably, life-long traditions and habits of thought will be hard to change, and all honest doubts arising from this quarter will merit sympathy and respect. Regarding opposition motivated by conscious self-seeking, no comment need be wasted. All but two of the first forty nation-wide editorials acclaimed the Voorhees report with enthusiasm, two were critical or neutral. Admittedly, this is only a beginning, but it appears to point the right direction. Those who presently face perplexing problems of medical and financial readjustment will want to read this report and draw their own conclusions

CATARACT IN CYCLOTRON WORKERS

THE recognition of cataracts apparently related to exposure to irradiation in 5 of the pioneer physicists working with cyclotrons brings a sad reminiscence of the early workers with x-rays and radium

However, there is a point of contrast. Cataract is a condition that can usually be operated upon and corrected successfully. The skin changes and the changes in the hematopoietic tissue of the early x-ray workers could not be corrected.

At the present time studies have not progressed to the point where any common factor in these cases, other than exposure to radiation from the cyclotrons, has been determined. However, there is some evidence that exposure of the eyes to neutrons if the worker looks into the beam of the cyclotron or directly into the target area is an important factor. This practice, once possible, has been eliminated by adequate safeguards.

It has been clearly established by experiments carried on under both the Manhattan Engineering District and the Atomic Energy Commission that, on the basis of the present methods of physical measurement, the biologic effectiveness of a given dose of neutrons as measured by physical means is greater than that of roentgen rays or gamma rays by a factor of 8 or 10 at least. This greater effectiveness hinges on the nature of the neutron, which carries no external electric charge, penetrates tissue readily and may hit several atoms, producing ionization at each hit.

One of the unfortunate aspects of the development of these cataracts is that they apparently were in a sense needless—that is, some persons at least departed from the known safety standards for operation and took what might be called a calculated risk (exceeding the known permissible dose of 0.1 r per day) deliberately to expedite the scientific work on which they were engaged. One of the continuing problems of all physicians and biophysicists having to do with safety monitoring is to counteract the natural enthusiasm of the scientist, which leads him to attempt shortcuts that appear reasonable from the standpoint of his science but are unsafe from the standpoint of biologic experience. In a sense, in establishing standards of permissible dose some recognition of this has been made since the standards under which the Atomic Energy Commission and its contractors operate, for example, are set with a very appreciable factor of safety. The standards permit continuing exposure over twenty or thirty years' time, with

safety Research is being initiated to determine the sensitivity of the lens to neutrons It has already been established as the most sensitive structure in the eye to roentgen rays

It is perhaps worth noting that in the making and handling of about $2\frac{1}{2}$ pounds of radium up to 1941, the total amount then isolated in the world, about 100 deaths may be ascribed to radium, only 2 deaths may be ascribed to the handling of material equivalent to hundreds of tons of radium under the Manhattan Project and the Atomic Energy Commission

THE NATURAL HISTORY OF DISEASE

MAN is subject to a great variety of diseases and it has always been one of the main functions of clinical research to provide accurate descriptions of these various pathologic entities The characteristics of most acute diseases and of the acute phases of most chronic diseases have been reasonably well defined With some notable exceptions, however, accurate descriptions of the entire courses of common, chronic conditions are woefully lacking

Essential hypertension is a case in point It is known that some patients with this disease rapidly develop incapacitating symptoms and that others go for many years without inconvenience of any sort It is also known that some patients develop a type of hypertension that proceeds with such extreme rapidity and is associated with such extensive vascular damage that the process is quite properly designated malignant The outlook for the patient with this form of the disease is undeniably bad, but what of the prognosis in a case of ordinary benign essential hypertension? Some investigators regard any type of hypertension as a highly dangerous disease, and believe that the prognosis is relatively poor The practicing physician is more apt to view mild or even moderate elevations in blood pressure with less alarm, knowing that many patients with hypertension remain asymptomatic for decades Neither view regarding the outlook in benign essential hypertension can be proved right or wrong, since most clinical descriptions of the disease cover too short a period in its course or are based on more or less selected case material That more adequate

studies are needed is very clear indeed, particularly to anyone who wishes to compare a group of treated with a group of untreated cases The advocates of sympathectomy for the treatment of benign essential hypertension have amassed an impressive amount of data on the effects of the operation up to ten years after surgery Unfortunately, it is still not possible to prove unequivocally that this or any other type of treatment significantly lengthen the life of the patient with benign essential hypertension What is lacking is a long-range study of a large number of unselected and untreated cases of the disease to serve as a base line The recent studies by Burgess¹ and by Bechgaard² are steps in the right direction, but many questions still remain unanswered

Another prominent example is duodenal ulcer the natural history of which remains shrouded in uncertainty and in which, as in essential hypertension, the value of the several forms of therapy cannot be determined until the course of the untreated disease is accurately mapped Still another example is glomerulonephritis, although many of the more pressing questions regarding the disease have recently been answered by Addis³ by means of a long-range study Cardiovascular degenerative disease is at last the focal point of an integrated attack by a group of investigators whose plans call for a ten-year period of study⁴

It is understandable, in view of the numerous difficulties involved, that relatively few investigators have undertaken long-range studies of disease Certainly, the general methods used by Addis and by Bechgaard are to be emulated when possible but there are other approaches to these problems There is, for example, a vast store of information locked up in the record rooms of hospitals and outpatient departments that could and should be ferreted out A record survey, particularly if combined with a determined attempt to follow up patients whether dead or alive, may prove to be an extremely valuable contribution Although the results of such a study may not be entirely applicable to a community as a whole, they at least provide information covering the hospital or outpatient department population Record research of this type is often looked upon as the stepchild of medical

investigative endeavor, but if pursued critically it always yields information of value. Furthermore, unless such use is made of hospital records, the careful recording and filing of clinical data loses much of its value and becomes increasingly hard to justify.

Data obtained by the military services can provide a starting point for inquiry into the natural history of certain diseases in young men. Several major research projects, utilizing such data have been initiated by the Veterans Administration. Furthermore, life-insurance statistics, although often based on highly selected samples, cannot be dismissed as valueless if the findings are not too broadly applied.

The time has surely come when the large gaps in the knowledge of long-term diseases should be closed. Not only should more long-range study projects be set up but also the data already at hand should be arranged and organized so as to obtain all possible information from it. It is decidedly paradoxical that so much investigative effort should have been spent on therapy when so little is known about the diseases against which the therapy is directed. The present trend toward long-range studies should remove the paradox and may go far toward enabling investigators to devise more rational and effective therapeutic methods.

FELLOWSHIP FOR FREEDOM

A "FELLOWSHIP for Freedom in Medicine," according to the *British Medical Journal*,* was formed by 700 British physicians at Caxton Hall, Westminster, on Saturday afternoon, November 13, 1948, Lord Horder being "unanimously acclaimed to the chair." The meeting was the eventual response to a letter from Lord Horder printed in the *British Medical Journal* in June, some 1750 letters had already been received as a result of this communication.

*National Health Service Fellowship for freedom in medicine. Supplement to the *British Medical Journal* 2 180 1948.

tion, and they were still arriving at the rate of 15 to 20 a day.

Among the reasons for the surrender of British medicine in the summer, Lord Horder averred, were "a secretariat swollen in numbers and influence, much going and coming between it and Whitehall, too strong a tail wagging too weak a dog, machinations, thought by many to be both meddlesome and mischievous, on the part of men holding key positions outside the [British Medical] Association" — (applause) — "and, if I may plagiarize Milton, 'blind mouths' at the centre and at the periphery 'hungry sheep' looking up but not being fed."

Part of the cause of the collapse, Lord Horder stated, was lack of an appreciation by the medical profession of its value in society. Its members let themselves be used "as pawns in the game instead of being master pieces."

"We are no longer experts," the chairman continued. "We sit and sign forms. With no time to diagnose their diseases, we pass our patients to other persons and to institutions, knowing full well that these cannot dispense the health benefits which may or may not be needed."

The sense of the meeting was that the standard of medical practice had fallen and was likely to fall still further, that the Fellowship for Freedom in Medicine should be in the nature of a guild to nurture the ideals of the profession until it might again be free.

British medicine may have become enslaved by politics, but it is apparently struggling inside its chains. Let American medicine look to itself that it may preserve its own freedom.

EASTER SEAL CAMPAIGN

THE Bay State Society for the Crippled and Handicapped, Inc., opens its fourth annual Easter Seal campaign today. The purpose of the drive is to raise \$275,000 — an increase of approximately \$73,000 over last year's receipts — for the support of six major treatment centers in the Commonwealth, as well as a program of medical care and employment for disabled persons, summer-camp vacations for handicapped children and prosthetic

devices for cripples. The projects operated or partially supported by this organization include a nursery school in Boston for children with cerebral palsy, a seizure unit at the Children's Hospital for the diagnosis and treatment of epilepsy, a curative workshop for the rehabilitation of the orthopedically handicapped and treatment and training centers for patients with cerebral palsy.

There is no denying the value—to the patient and the community alike—of rehabilitation and training of disabled persons. The campaign, whose success will ensure continued functioning of these vitally necessary activities, deserves the active support of physicians and laymen alike.

CORRESPONDENCE

OCCUPATIONAL MEDICAL CLINIC AT MASSACHUSETTS GENERAL HOSPITAL

To the Editor From 1911 to 1928 the Massachusetts General Hospital conducted what was known as the Industrial Clinic for the study and care of workers thought to be disabled because of occupational hazard.

On February 1, 1949, this work was revived at the Massachusetts General Hospital with the slightly broader title, Occupational Medical Clinic. Supported by funds from the National Institute of Health, Research Grants Division of the United States Public Health Service, and the Massachusetts General Hospital, the work is to be investigative in nature. Affiliation of the Occupational Medical Clinic with the Massachusetts Division of Occupational Hygiene will make possible correct evaluation of the hazards in the worker's environment capable of causing disease. Inpatient study in a small way is planned, and outpatients will be seen regularly at the request of any physician. No traumatic cases will be handled. Proper diagnosis, delineation of previously unrecognized occupational illness and study of better forms of management of worker disability are the concern of the Occupational Medical Clinic. After study, worker patients will be referred to their private physicians for care. The initial visit will be on a regular outpatient basis, but no charge will be made to patients who are accepted for study in the Occupational Medical Clinic, since this is a research project.

TOWN MEETING OF DOCTORS

A Town Meeting of Doctors will be held at the Massachusetts General Hospital, Lower Out-patient Department Amphitheater, on Monday, March 21, at 8 p.m. There will be a discussion of controversial issues from Mr. Ewing's report "The Nation's Health—A Ten-Year Program."

2. Enough Hospitals Everywhere

COUNCIL OF THE NEW ENGLAND STATE MEDICAL SOCIETIES

A meeting of the Council of the New England State Medical Societies will be held in the Oval Room of the Copley Plaza Hotel, Boston, on Sunday, March 27.

PROGRAM

1 30 p.m. Call to Order
Greetings Stephen A. Cobb, M.D., president, Council of the New England State Medical Societies and past president, Maine Medical Association.

- 1 45 p.m. The National Education Campaign of the American Medical Association. Clem Whitaker, campaign director, and Leone Baxter, general manager.
- 2 45 p.m. The Special A.M.A. Assessment. James R. Miller, M.D., Trustee, American Medical Association and past president, Council of the New England State Medical Societies.
- 3 15 p.m. Extending Medical Care in New England through Medical-Society Sponsored Voluntary Plans (A five-minute report by a delegate from each of the six state medical societies).
- 3 45 p.m. Extending Medical Care in New England through Insurance-Company Programs. Henry D. Locke, research director, Liberty Mutual Insurance Company, Boston.
- 4 15 p.m. Discussion from the Floor (Officers and Committee members of state and county medical societies are invited to discuss the topics presented, and to ask questions of the speakers).
- 5 15 p.m. Adjournment.

NEW ENGLAND HEART ASSOCIATION

A meeting of the New England Heart Association will be held in the Auditorium of Building E, Harvard Medical School, on Monday, March 28, at 8 00 p.m., Doctor Herrman L. Blumgart presiding.

PROGRAM

- Experimental Fluorocardiography with Simultaneous Recording of Intracardiac Pressure. Drs. Aldo A. Lusada and Felix G. Fleischner.
- Appraisal of the Size of the Right Ventricle in the Lateral View. Dr. Felix G. Fleischner.
- Spontaneous Cardiac Rupture. A clinicopathological study of fourteen cases. Drs. Stanford Wessler, Monroe J. Schlesinger and Paul M. Zoll.
- Experimental Studies of the Cardiac Action of Quinidine. Dr. Arthur J. Linenthal.
- The Role of Anemia in the Production of Interarterial Coronary Anastomoses. Drs. Paul M. Zoll, Monroe J. Schlesinger and Stanford Wessler.
- Treatment of Euthyroid Cardiac Patients by Producing Hypothyroidism with Radioactive Iodine.
- The Method of Producing Hypothyroidism. Drs. A. Stone, Freedberg, George Kurland and Alvin L. Ureles.
- Clinical Results in Angina Pectoris and Congestive Failure. Drs. Herrman L. Blumgart, A. Stone, Freedberg and George Kurland.

To complete the program by 10 00 p.m., the meeting will begin at 8 00 p.m.

Interested physicians and medical students are cordially invited to attend.

ALUMNI OF CHILDREN'S HOSPITAL, WASHINGTON, D. C.

An organization of the Alumni of Children's Hospital, Washington, D. C., is being undertaken. The Children's Hospital Alumni Charter Meeting will be held on April 5 in Washington, D. C.

VIRAL HEPATITIS*

A Consideration of Certain Aspects of Current Importance to the Practicing Physician

JOHN R. NEEFE, M.D.†

PHILADELPHIA

DURING recent years, the importance of viral hepatitis as a public-health and military problem has become increasingly apparent. The term "viral hepatitis" is used to include as a group the forms of hepatitis caused by filterable infectious agents that apparently are primarily hepatotropic and produce, as their outstanding clinical manifestations, evidences of liver injury that may or may not be associated with phenomena suggesting an infectious origin.

Viral hepatitis thus includes the two types of disease commonly referred to as infectious (epidemic) and homologous serum hepatitis. The available evidence indicates that at least two filterable agents, which tentatively can be classified as viruses, are concerned¹⁻⁵. One, referred to below as virus IH, has been identified primarily with the clinical and epidemiologic syndrome of infectious (epidemic) hepatitis, which usually has an incubation period of fifteen to forty days. It perhaps has not been generally recognized that this virus may also be responsible for so-called "homologous serum hepatitis" occurring fifteen to forty days after "parenteral exposure" to a source of the virus through one of the mechanisms discussed below. More familiar is the classic syndrome of homologous serum hepatitis, the most distinctive feature of which is the long interval of two to four and a half months that elapses between "parenteral exposure" and the onset of the overt disease. The other of the two viruses mentioned above, and subsequently referred to as virus SH, appears to be mainly responsible for this syndrome. Homologous serum hepatitis thus should not be regarded as a single etiologic entity.

Evidence for the existence of at least these two hepatitis viruses (IH and SH types) has been

described in detail elsewhere¹⁻⁵. Further discussion here does not seem warranted except to call attention to the fact that the differences that have been demonstrated between these two types of hepatitis virus stand strongly on the mutually confirmatory experimental results obtained by three independent groups of investigators¹⁻⁵ and are supported by a large body of epidemiologic evidence^{1, 6, 7}. Efforts to account for the various syndromes of viral hepatitis on the basis of a single virus fail to explain the consistent short incubation period following parenteral injection of IH viruses, the failure of SH viruses to induce overt disease when administered orally, and the lack of resistance (cross immunity) to infection by one virus in the presence of resistance (homologous immunity) to reinfection by the other.

At the present time, however, the problems presented by the two recognized types of viral hepatitis overlap, and, as no clinically applicable method for their specific differentiation has been developed, it is practical and useful to consider them together under the group term "viral hepatitis."

PUBLIC-HEALTH ASPECTS

Considered in the above sense, viral hepatitis is a widespread disease of high sporadic and epidemic incidence. The actual incidence must be considerably higher than the apparent incidence since the disease unfortunately is not universally reportable and because many cases, particularly those in which jaundice does not become overt, are unrecognized. The recognized cases alone, however, are sufficiently frequent to warrant recognition of viral hepatitis as an existing and potential public-health problem of major importance.

SPECIAL PROBLEMS IN DIAGNOSIS AND MANAGEMENT

Of considerable interest and clinical significance is the fact that viral hepatitis is being recognized with increasing frequency as an important cause of jaundice in the older age groups. Most of the infections in these patients appear to be of the virus

(Notices concluded on page xiii)

No extrahuman host has as yet been recognized. Therefore, discussion must at present start and end with the human host (Fig 1). Hepatitis viruses IH and SH may both be acquired from human blood. Only the former has been shown to be present in the feces. Neither has been proved conclusively to be present, or absent, in urine and nasopharyngeal secretions, but present information suggests that these are not potent sources of hepatitis virus, at least during the active stages of the disease. Transmission of hepatitis virus IH from feces through one or more of the mechanisms shown in Figure 1 probably accounts

signs, it is not known whether the virus persists or recurs in the blood after recovery from acute hepatitis, development of a method for inactivating the virus in whole blood or plasma will solve only part of the problem, the virus in human serum albumin solutions is apparently inactivated by present methods of processing (heating at 60°C for ten hours). In Figure 1, the recognized mechanisms through which the hepatitis virus may be acquired from blood are enclosed in solid lines. Three of these — namely, the use of human blood, plasma or serum for transfusion, passive immunization and as a component of biologicals — are well established

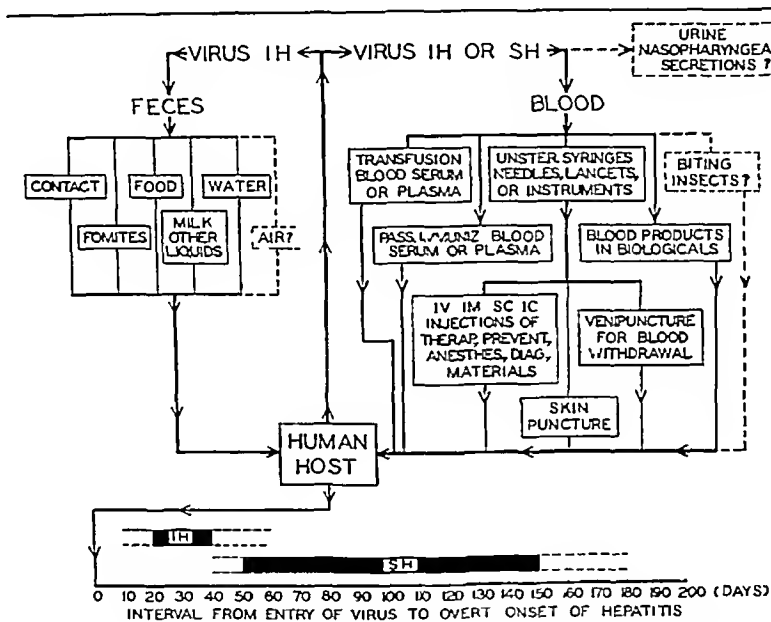

FIGURE 1 Concept of the Etiology and Epidemiology of Viral Hepatitis

for a large proportion of the naturally acquired infections, both sporadic and epidemic. At the present time, there is little that one can do to interrupt this chain of events other than apply the usual sanitary measures indicated for control of all intestinal pathogens.

The mechanisms of transfer of hepatitis virus through blood and its derivatives are of particular interest. The special factors involved in the prevention of blood transmission include the fact that minute quantities (0.01 cc or less) are infective, all methods developed to date that are capable of inactivating the virus in blood or plasma render these materials unsatisfactory or unsafe for human use, there is as yet no practical method for detecting the virus in blood or plasma, and no method for detecting infected donors, as pointed out above, the viruses may appear in the blood without previous, associated or subsequent symptoms or

links in the epidemiologic chain.¹ Transmission through these mechanisms is not yet completely preventable, but the frequency can be decreased by recognition and adherence, so far as possible, to the following principles: transfusion of the blood, plasma or serum should be avoided whenever possible and used only when the indication is greater than the risk (the choices in order of increasing risk are human serum albumin, whole blood, single plasma units, cross-matching beings required, small plasma pools and large plasma pools), donors should be excluded if they have been exposed to a potential source of the virus during the preceding six months, if they have had unexplained or positive symptoms during the previous six months or if icterus, hepatomegaly and positive laboratory findings are present at the time of bleeding, the recipient's record should contain data identifying the product received, and the blood-bank record should

SH type, and the increased incidence probably results in part from the greater frequency with which older persons are being exposed to the mechanisms whereby blood transmission of virus may occur. Possible explanations for the apparent predominance of virus SH types of infection in the older age groups have been discussed elsewhere.¹ Suffice it to say here that viral hepatitis not only is the most frequent cause of jaundice in children and young adults but also must now be regarded as a frequent cause of jaundice in older persons. This is of considerable clinical significance because the onset, particularly of the SH type, frequently is relatively silent and the course initially may resemble that of the familiar clinical picture of malignant or mechanical obstruction of the extrahepatic biliary tract, with progressively increasing jaundice and, occasionally, clay-colored stools. Phenomena suggesting an infectious origin are frequently absent. Recognition and accurate differential diagnosis are of extreme importance, since surgical exploration of the patient with acute hepatitis is associated with a high mortality. It is essential, therefore, that viral hepatitis be considered as a possibility in every jaundiced patient regardless of age.

Aside from the difficulties viral hepatitis presents in differential diagnosis, the disease, even when recognized, constitutes a further problem in management and disposition. This results from the fact that the duration of disability and incapacitation in the favorable uncomplicated overt case averages approximately six weeks. Even under the best of conditions a small percentage of patients suffer disability for longer periods as a result of the tendency of the disease to relapse, and, in a still smaller percentage, to become chronic. Although the overall mortality is low, estimated in large outbreaks as approximately 0.2 per cent, it has been as high as 20 per cent in certain small outbreaks.¹ Viral hepatitis, therefore, is never to be regarded lightly, and the initial course of the disease frequently provides no clinical warnings of an impending relapse or fatal outcome. These tendencies to natural relapse and chronicity, or fatal termination, may be exaggerated by delayed recognition and improper management. Early recognition and treatment are therefore of considerable importance. In addition, it is during the first and second weeks of jaundice that the intelligent use of a group of hepatic tests provides the most reliable and helpful assistance in differential diagnosis. All too frequently the performance of such studies early in the disease is deferred in the hope that the jaundice will subside or the cause will become obvious with the passage of time and that the patient thereby will be saved the expense and trouble of laboratory studies. The importance of obtaining a "baseline" group of hepatic tests in every jaundiced patient within the first two weeks of jaundice cannot be overemphasized. With few exceptions,

clinical phenomena cannot be depended upon for differential diagnosis, and the proper decision between medical and surgical treatment is at times life saving. For this reason, every jaundiced patient deserves prompt laboratory investigation regardless of how typical the clinical phenomena appear. As the maximum diagnostic assistance from laboratory investigations is obtained soon after jaundice is detected, failure to take advantage of such assistance at that time may be regretted later. It is not implied that laboratory tests alone will differentiate "medical" and "surgical" jaundice. Properly selected and interpreted tests applied at the right time, however, will substantially increase the incidence of correct differentiation of those two conditions or, at least, will assist in the decision concerning immediate, if not ultimate, management.

NEWER ASPECTS OF ETIOLOGY AND EPIDEMIOLOGY

The increasing medicolegal importance of viral hepatitis deserves special comment. Unfortunately, the available information indicates that a considerable, as yet unestimable, proportion of the cases of viral hepatitis are consequences of certain indispensable technics of medical practice. This is of great immediate concern to all, for it not only threatens the continued use of some of the most important and irreplaceable therapeutic weapons, blood and plasma, but also potentially involves certain costly, protracted and difficult changes in medical technic, which, ignored or not recognized, may occasionally lead to suits for malpractice.

An example is an incident, recently described in the foreign-correspondence section of the *Journal of the American Medical Association*,⁸ that resulted in the imprisonment of a physician in Italy. The justifications for the action taken in this case cannot be evaluated from the data presented, but the episode serves as a warning of the potential dangers involved.

Time does not permit a detailed discussion of this problem. It is possible only to point out, in a general way, some of the matters involved. Figure 1 represents an attempt to portray diagrammatically a tentative working concept of the etiology and epidemiology of viral hepatitis. Some of the general factors concerned in the transmission of hepatitis are as follows: blood and feces are the only proved sources of hepatitis virus, which is apparently present in high concentration, since extremely small quantities may be infectious, the viruses survive for long periods under variable conditions and resist many procedures that eliminate or inactivate most infectious agents, including desiccation, extremes of temperature, filtration, commonly used plasma preservatives (such as merthiolate) and chlorination of water under certain conditions, the virus may be present in blood or feces without previous, associated or subsequent symptoms or signs.

No extrahuman host has as yet been recognized. Therefore, discussion must at present start and end with the human host (Fig 1). Hepatitis viruses H and SH may both be acquired from human blood. Only the former has been shown to be present in the feces. Neither has been proved conclusively to be present, or absent, in urine and nasopharyngeal secretions, but present information suggests that these are not potent sources of hepatitis virus, at least during the active stages of the disease. Transmission of hepatitis virus IH from feces through one or more of the mechanisms shown in Figure 1 probably accounts

signs, it is not known whether the virus persists or recurs in the blood after recovery from acute hepatitis, development of a method for inactivating the virus in whole blood or plasma will solve only part of the problem, the virus in human serum albumin solutions is apparently inactivated by present methods of processing (heating at 60°C for ten hours). In Figure 1, the recognized mechanisms through which the hepatitis virus may be acquired from blood are enclosed in solid lines. Three of these — namely, the use of human blood, plasma or serum for transfusion, passive immunization and as a component of biologicals — are well established

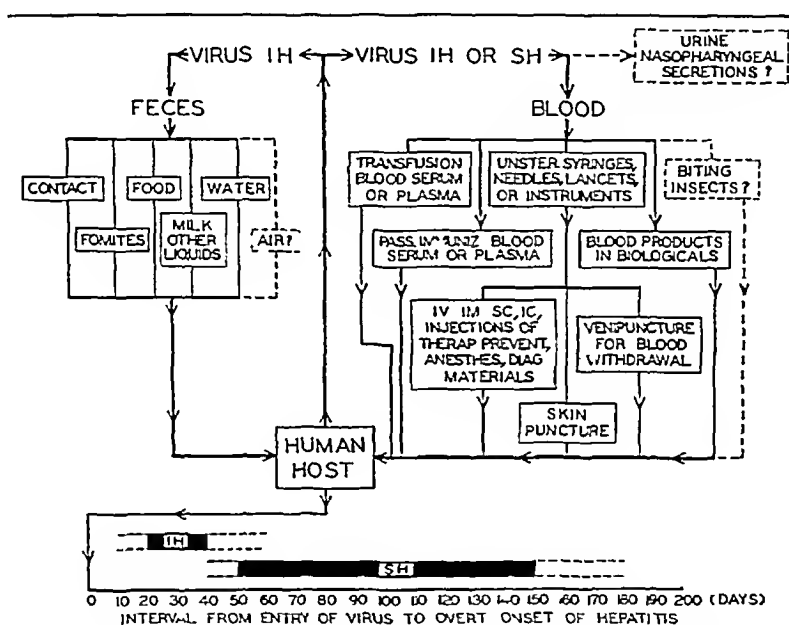

FIGURE 1 Concept of the Etiology and Epidemiology of Viral Hepatitis

for a large proportion of the naturally acquired infections, both sporadic and epidemic. At the present time, there is little that one can do to interrupt this chain of events other than apply the usual sanitary measures indicated for control of all intestinal pathogens.

The mechanisms of transfer of hepatitis virus through blood and its derivatives are of particular interest. The special factors involved in the prevention of blood transmission include the fact that minute quantities (0.01 cc or less) are infective, all methods developed to date that are capable of inactivating the virus in blood or plasma render these materials unsatisfactory or unsafe for human use, there is as yet no practical method for detecting the virus in blood or plasma, and no method for detecting infected donors, as pointed out above, the viruses may appear in the blood without previous, associated or subsequent symptoms or

links in the epidemiologic chain.¹ Transmission through these mechanisms is not yet completely preventable, but the frequency can be decreased by recognition and adherence, so far as possible, to the following principles: transfusion of the blood, plasma or serum should be avoided whenever possible and used only when the indication is greater than the risk (the choices in order of increasing risk are human serum albumin, whole blood, single plasma units, cross-matching beings required, small plasma pools and large plasma pools), donors should be excluded if they have been exposed to a potential source of the virus during the preceding six months, if they have had unexplained or positive symptoms during the previous six months or if icterus, hepatomegaly and positive laboratory findings are present at the time of bleeding, the recipient's record should contain data identifying the product received, and the blood-bank record should

identify the recipients and donors. Furthermore, failure to recognize and weigh the potential risk may have important medicolegal implications.

A fourth mechanism, although difficult to prove directly, is supported by a large body of epidemiologic evidence.⁹⁻²² It must therefore be recognized that the hepatitis virus may be transmitted by means of improperly sterilized syringes, needles, lancets and other instruments that have been in contact with human blood (Fig 1). As such transmission is preventable, all practical precautions must be taken. Although it is difficult and perhaps impossible to prove infection of individual cases by this mechanism, failure to recognize the potentialities is again of medicolegal importance and formed the basis of the case against the Italian physician cited above. Some of the possible means by which the hepatitis virus may gain access to a person through the medium of inadequately sterilized instruments are shown in Figure 1 as sub-headings under this mechanism.

Finally, the potential role of insect bites in the transmission of these viruses in blood is mentioned (broken lines, Fig 1), although there is as yet no direct evidence of natural transmission in this way.

SUMMARY

Viral hepatitis is presented as a widespread disease of high sporadic and epidemic incidence caused by at least two, primarily hepatotropic, filterable, infectious agents whose outstanding clinical manifestation is evidence of hepatic injury with or without associated phenomena suggesting an infectious origin.

The fact that viral hepatitis involves all age groups is emphasized, and its apparently increasing frequency as a cause of jaundice in the older age groups is discussed, particularly in relation to the importance of its consideration in every jaundiced patient regardless of age and the clinical phenomena.

The public-health, military, and individual significance of the disease is stressed, with special reference to morbidity, mortality and its unfortunate relation to certain indispensable medical technics.

The increasing medicolegal importance of the disease to the practicing physician is emphasized. This new aspect has developed with the recent recognition of the potential relation between viral hepatitis and certain medical technics. This relation is illustrated by reference to a diagram summarizing the available knowledge concerning the sources of the hepatitis viruses and the mechanisms by which they are transferred from person to person. The responsibility of the physician in the interruption of certain of these potential mechanisms is indicated.

A SURVEY OF RECENT THERAPEUTIC MEASURES IN CIRRHOSIS OF THE LIVER*

THOMAS C. CHALMERS, M.D.,† AND CHARLES S. DAVIDSON, M.D.‡

BOSTON

ELEVEN years have elapsed since Patek's first reported the effectiveness of a nutritious diet in the treatment of cirrhosis of the liver. On the basis of the rapidly accumulating evidence that cirrhosis can be produced in animals on a low-protein diet and prevented by the addition of certain food factors,¹⁻³ a nutritious diet accompanied by abstinence, when there is a history of alcohol addiction, is now the accepted method of treatment. In this communication consideration is given to certain practical aspects of the dietary treatment of cirrhosis, particularly the quantity of fat allowed, the place of vitamin and specific amino acid supplements and the importance of a low-sodium diet in the control of ascites and edema. In addition a critique is presented of the more recent method of treatment of patients with esophageal varices and ascites who are not improved by dietary means alone.

The recently reported experiences of Patek's group⁴⁻⁶ in the dietary treatment of cirrhosis are summarized in Table 1. It should be pointed out that the controls were taken from nospital admissions between the years 1920 and 1940 when other important therapeutic measures such as chemotherapy and blood transfusions were not as generally available as they have been in the last ten years. The results are nevertheless impressive and have been confirmed,⁷⁻¹¹ and in spite of the absence of a better controlled series the importance of a nutritious diet in the treatment regime seems well established.

The mere prescription of such a diet is not sufficient. A patient with cirrhosis may have severe anorexia and must be tempted with an attractive menu. He may have to be fed by attendants or maintained by tube or parenteral feeding until his appetite returns. That there is still room for improvement in the treatment of cirrhosis even under the ideal conditions of a research service is shown by the fact that only 61 of 124 cases treated by Patek's group showed clinical improvement fulfilling the following three criteria: gain in weight and strength, disappearance of ascites, edema and jaundice, and changes toward normal values of the liver-function tests.⁴

A number of observers believe that fat should be restricted in the diet provided to patients with liver disease. This conception probably has arisen from the evidence that a high-fat intake hastens the appearance of cirrhosis in animals on a low-protein diet and secondly that patients with biliary-tract obstruction generally have a fatty-food intolerance. In experimental animals, however, an adequate protein diet protects the liver from the injurious effects of fat. Moreover, patients with cirrhosis rarely have a fatty-food intolerance. Indeed Patek's⁵ patients were given 175 gm. of fat a day, together with 365 gm. of carbohydrate and 140 gm. of pro-

tein. This amount of fat is necessary to ensure palatability of the diet, and no ill effects were noted by Patek in his patients. Restricting the fat content to 50 gm. a day is advocated by some,^{10, 11} results in an unpalatable, low-calorie diet that discourages the patient from taking the "one medicine" really important for him — food. Thus, no restriction of fat in the diet of patients with cirrhosis seems indicated unless obesity makes a restriction in calories necessary.

The history of prolonged poor food intake, together with signs suggestive of vitamin deficiency present in some cirrhotic patients, has made the addition of vitamin supplements to most treatment regimes common. However, some doubt has been cast on the need for the administration of large quantities of purified vitamins. It is generally agreed that the liver is a storehouse for both the water-soluble and fat-soluble vitamins and that these stores are reduced in a cirrhotic liver. But the signs thought to be due to vitamin deficiency often do not respond as well to vigorous treatment as they do in patients without liver disease. It has been suggested¹² that in some patients with cirrhosis there exists an intrinsic rather than extrinsic deficiency — that is, a diminished ability of the liver to utilize the vitamins supplied to it (for example, as coenzymes). In addition, it is theoretically pos-

identify the recipients and donors. Furthermore, failure to recognize and weigh the potential risk may have important medicolegal implications.

A fourth mechanism, although difficult to prove directly, is supported by a large body of epidemiologic evidence.^{9,22} It must therefore be recognized that the hepatitis virus may be transmitted by means of improperly sterilized syringes, needles, lancets and other instruments that have been in contact with human blood (Fig 1). As such transmission is preventable, all practical precautions must be taken. Although it is difficult and perhaps impossible to prove infection of individual cases by this mechanism, failure to recognize the potentialities is again of medicolegal importance and formed the basis of the case against the Italian physician cited above. Some of the possible means by which the hepatitis virus may gain access to a person through the medium of inadequately sterilized instruments are shown in Figure 1 as sub-headings under this mechanism.

Finally, the potential role of insect bites in the transmission of these viruses in blood is mentioned (broken lines, Fig 1), although there is as yet no direct evidence of natural transmission in this way.

SUMMARY

Viral hepatitis is presented as a widespread disease of high sporadic and epidemic incidence caused by at least two, primarily hepatotropic, filterable, infectious agents whose outstanding clinical manifestation is evidence of hepatic injury with or without associated phenomena suggesting an infectious origin.

The fact that viral hepatitis involves all age groups is emphasized, and its apparently increasing frequency as a cause of jaundice in the older age groups is discussed, particularly in relation to the importance of its consideration in every jaundiced patient regardless of age and the clinical phenomena.

The public-health, military, and individual significance of the disease is stressed, with special reference to morbidity, mortality and its unfortunate relation to certain indispensable medical technics.

The increasing medicolegal importance of the disease to the practicing physician is emphasized. This new aspect has developed with the recent recognition of the potential relation between viral hepatitis and certain medical technics. This relation is illustrated by reference to a diagram summarizing the available knowledge concerning the sources of the hepatitis viruses and the mechanisms by which they are transferred from person to person. The responsibility of the physician in the interruption of certain of these potential mechanisms is indicated.

A SURVEY OF RECENT THERAPEUTIC MEASURES IN CIRRHOSIS OF THE LIVER*

THOMAS C CHALMERS, M.D.,† AND CHARLES S DAVIDSON, M.D.‡

BOSTON

ELEVEN years have elapsed since Patek¹ first reported the effectiveness of a nutritious diet in the treatment of cirrhosis of the liver. On the basis of the rapidly accumulating evidence that cirrhosis can be produced in animals on a low-protein diet and prevented by the addition of certain food factors,²⁻⁵ a nutritious diet accompanied by abstinence, when there is a history of alcohol addiction, is now the accepted method of treatment. In this communication consideration is given to certain practical aspects of the dietary treatment of cirrhosis, particularly the quantity of fat allowed, the place of vitamin and specific amino acid supplements and the importance of a low-sodium diet in the control of ascites and edema. In addition a critique is presented of the more recent method of treatment of patients with esophageal varices and ascites who are not improved by dietary means alone.

The recently reported experiences of Patek's group⁶⁻⁸ in the dietary treatment of cirrhosis are summarized in Table 1. It should be pointed out that the controls were taken from hospital admissions between the years 1920 and 1940, when other important therapeutic measures such as chemotherapy and blood transfusions were not as generally available as they have been in the last ten years. The results are nevertheless impressive and have been confirmed,⁹⁻¹¹ and in spite of the absence of a better controlled series the importance of a nutritious diet in the treatment regime seems well established.

The mere prescription of such a diet is not sufficient. A patient with cirrhosis may have severe anorexia and must be tempted with an attractive menu. He may have to be fed by attendants or maintained by tube or parenteral feeding until his appetite returns. That there is still room for improvement in the treatment of cirrhosis even under the ideal conditions of a research service is shown by the fact that only 61 of 124 cases treated by Patek's group showed clinical improvement fulfilling the following three criteria: gain in weight and strength, disappearance of ascites, edema and jaundice, and changes toward normal values of the liver-function tests.

A number of observers believe that fat should be restricted in the diet provided to patients with liver disease. This conception probably has arisen from the evidence that a high-fat intake hastens the appearance of cirrhosis in animals on a low-protein diet, and secondly that patients with biliary-tract obstruction generally have a fatty-food intolerance. In experimental animals, however, an adequate protein diet protects the liver from the injurious effects of fat. Moreover, patients with cirrhosis rarely have a fatty-food intolerance. Indeed, Patek's⁸ patients were given 175 gm of fat a day, together with 365 gm of carbohydrate and 140 gm of pro-

sible that niacin in large doses may be harmful to patients with fatty livers. Since a portion of administered niacin is excreted as the methyl derivative, the vitamin has been given to animals to hasten the development of cirrhosis on a deficient diet by reducing the effectiveness of choline and methionine.¹³ Gillman and Gillman¹⁴ found that pellagrous children with fatty livers became worse when given large quantities of vitamins, whereas

In a disease as chronic and at the same time as variable in its course as cirrhosis it is extremely difficult to assess the efficacy of a single therapeutic measure. Adequate controls are necessary, and yet many of the reports of the clinical use of methionine and choline in cirrhosis are uncontrolled.¹⁵⁻¹⁷ In four recent studies with controls^{10, 11, 18, 19} the groups given choline or methionine showed an apparent decrease in mortality rate and somewhat greater and faster improvement than those treated with a nutritious diet alone, but the size of each group was too small to be significant and the method of selecting cases not always clear. Larger numbers of patients, strictly alternated, control and treated, are necessary to eliminate effects resulting from the many uncontrolled variables encountered in such a study. Finally, a nutritious diet furnishes in itself relatively large amounts of choline and methionine. Until the science of nutrition has become exact enough to indicate all the nutrients necessary in health and disease and the precise quantities required, it seems better to supply those nutrients as food rather than purified chemicals.

If the physician cannot induce the patient to eat a nutritious diet, crude food complements such

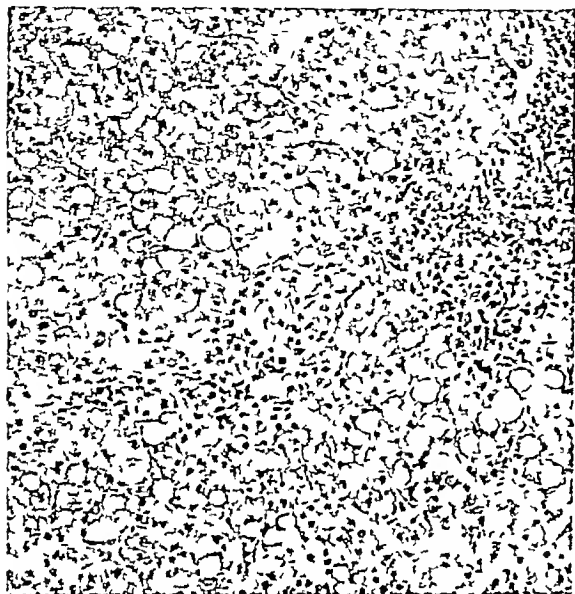

FIGURE 1 *Punch Biopsy of the Liver of a Chronic Alcoholic Patient Who Entered the Hospital Deeply Jaundiced and Close to Delirium Tremens*

There is moderate fatty metamorphosis and cellular infiltration

the fat rapidly disappeared from their livers on treatment with dried hog's stomach. They suggested that the poor results of massive vitamin therapy might be due to an antilipotropic effect of niacin. Since, therefore, large doses of the purified vitamins do not appear necessary and may be harmful, it seems wise to administer them only in the usual therapeutic quantities, or better to rely on the nutritious diet and, if necessary, crude food supplements may be given in addition.

Three nutrients that have been shown to be important in the prevention and treatment of experimental dietary liver injury in animals are choline, a source of methyl groups, and the sulfur-containing amino acids, methionine and cystine. Methionine is also an important source of methyl groups for the synthesis of choline. The exact modes of action of these substances and the possible existence of others are the subjects of present research. However, since methionine and choline have already been used rather extensively in the clinical treatment of liver disease, it is important to determine whether or not they are useful

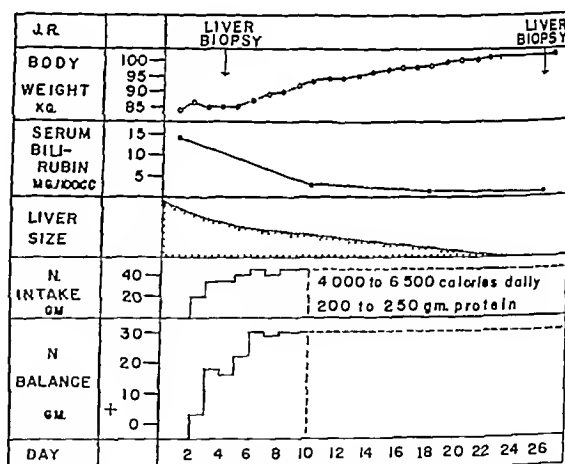

FIGURE 2 *Clinical Course of the Patient Whose Biopsies Are Shown in Figure 1 and 3*

as brewer's yeast powder, high-protein milk drinks and liver products by mouth, intramuscularly or intravenously, may be employed. Labby and his associates²⁰ reported excellent results, primarily in the form of appetite stimulation, with frequently administered intravenous crude liver extract, but here again simultaneous controls were lacking and their patients were in general of a higher economic and social stratum than the usual charity-hospital population, and thus were more amenable to all forms of therapy.

The dramatic improvement that may take place in patients with liver disease who eat well is illustrated by the course of a thirty-five-year-old longshoreman who entered the Boston City Hospital deeply jaundiced and close to delirium tremens after a prolonged drinking bout during which he ate almost nothing. A punch biopsy taken before treatment (Fig 1) shows the fatty metamorphosis characteristic of the liver cells in such patients and, in addition, a quite marked cellular infiltration around the portal areas. Figure 2 summarizes the patient's clinical course. His appetite was excellent, food intake (without supplements) was enormous, and he retained a considerable proportion of the nitrogen administered. He gained 15 kg (33 pounds), and his serum bilirubin and liver size rapidly receded to normal. Figure 3 shows his liver three weeks after therapy was begun, essentially normal. Thus early changes in the liver may be completely reversible if the patient stops drinking and eats well. This patient could hardly have im-

proved more rapidly had choline and methionine been added to his diet. The rapid recovery to be expected in early cirrhosis as contrasted with the later forms of the disease has been observed by several investigators²¹⁻²³. Indeed, it is becoming increasingly apparent that many alcoholic patients with early cirrhosis may live out their normal life span if they abstain from alcohol while continuing to eat a nutritious diet. This fact emphasizes the need for finding early cases by the freer use of sensitive liver-

function tests and punch biopsy as part of any attempt to reduce the mortality from the disease. In fact, all of 24 patients entering the Boston City Hospital with delirium tremens but without significant clinical signs of cirrhosis were found by punch biopsy to have abnormal amounts of fat in their livers and 14 to have early, asymptomatic fibrosis.²³ Gratifying results can be obtained in this group of patients, so large in any charity hospital, if intensive treatment is instituted by the

FIGURE 4 Punch Biopsy of the Liver of a Chronic Alcoholic Patient with Massive Ascites Who Had Been Treated for Three Months with a Highly Nutritious Diet

Fairly normal-appearing liver cells are encased in thick bands of fibrous tissues

combined efforts of internist, psychiatrist and social worker.

In the treatment of the more chronic forms of liver disease other problems are encountered, especially recurrent ascites. Figure 4 is a photomicrograph of a biopsy of the liver of a chronic alcoholic patient who entered the hospital with massive ascites and who for three months before biopsy required frequent paracenteses although he was treated vigorously with a nutritious diet and almost daily intravenous liver extract. The biopsy section reveals fairly normal liver cells encased in thick bands of fibrous tissue. This is the kind of stabilized patient referred to as having intractable ascites — the kind who feels and eats well but requires frequent paracenteses and who, although he may occasionally be freed of ascites, may die at any time of bleeding from ruptured esophageal varices.

How much dietary treatment can do for the patient with cirrhosis who is relatively asymptomatic except for episodes of hematemesis has not been established. It is doubtful whether diet can alter the fibrous tissue that obstructs the hepatic circulation and shifts large amounts of blood from the liver into the collaterals. Reports of such sur-

sible that niacin in large doses may be harmful to patients with fatty livers. Since a portion of administered niacin is excreted as the methyl derivative, the vitamin has been given to animals to hasten the development of cirrhosis on a deficient diet by reducing the effectiveness of choline and methionine.¹³ Gillman and Gillman¹⁴ found that pellagrous children with fatty livers became worse when given large quantities of vitamins, whereas

In a disease as chronic and at the same time as variable in its course as cirrhosis it is extremely difficult to assess the efficacy of a single therapeutic measure. Adequate controls are necessary, and yet many of the reports of the clinical use of methionine and choline in cirrhosis are uncontrolled.¹⁵⁻¹⁷ In four recent studies with controls^{10 11 13 19} the groups given choline or methionine showed an apparent decrease in mortality rate and somewhat greater and faster improvement than those treated with a nutritious diet alone, but the size of each group was too small to be significant and the method of selecting cases not always clear. Larger numbers of patients, strictly alternated, control and treated, are necessary to eliminate effects resulting from the many uncontrolled variables encountered in such a study. tients were neither treated nor followed long enough*.

Responses just as erratic as those after albumin administration have been seen in patients treated with diet alone and in those given mercurial diuretics. In an effort to find a common metabolic defect altered in patients showing a response to these several measures, sodium-balance studies were performed by Faloon et al.⁴¹ The patients with decompensated cirrhosis were found to be unable to excrete administered sodium except in very small amounts. When diuresis occurred,

but with 6 gm of sodium chloride given in addition. He remained in positive sodium and water balance, gained 12 pounds in weight and required an average of 20 gm of albumin a day to maintain a normal serum albumin concentration. On withdrawal of the added 6 gm of salt his sodium balance became negative, and he stopped gaining weight and required daily only 11 gm of albumin to maintain the same serum albumin concentration.

The mechanism of this inability to excrete sodium is obscure, but the therapeutic implications are obvious. The frequency of abdominal paracentesis

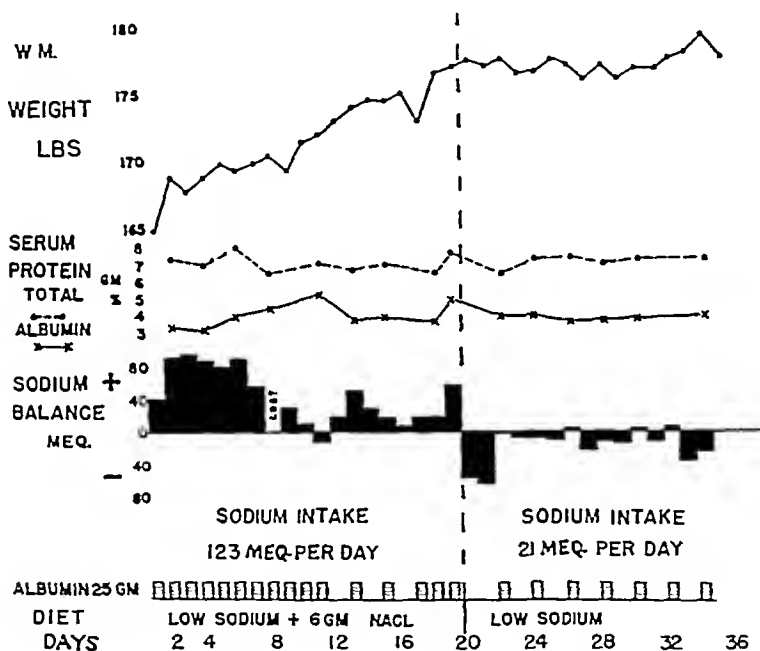

FIGURE 5 *The Effect of Sodium Restriction in the Diet of a Patient Who Is Accumulating Ascites*

The serum albumin level had previously been raised to normal by intravenous concentrated salt-poor human albumin. This was continued at a rate necessary to maintain the serum albumin at a normal level.

whether spontaneous or accompanying albumin or mercurial administration, urinary sodium rose markedly and a negative sodium balance ensued.

Figure 5 illustrates the effect of withholding salt from the diet of a patient who had required frequent paracenteses in spite of a serum protein concentration maintained at normal by the intravenous administration of albumin. Over a twenty-day period he was provided with a low-sodium diet, containing about 1.25 gm of sodium chloride a day,

can be reduced if the patient is maintained on a low-sodium diet supplemented, if desired, by ammonium chloride and mercurial diuretics. Concentrated human albumin is an expensive and in some cases perhaps a somewhat dangerous adjunct to this regime. The best results of albumin administration are seen in patients with massive edema and ascites who have not required paracentesis. The importance of restricting salt is best illustrated by the following calculations. Extrarenal loss of sodium chloride under moderate temperature conditions has been found to remain fairly constant, at about 1 gm a day.^{42, 43} Urinary loss in a cirrhotic patient who is accumulating ascites is rarely more than 0.5 gm a day, regardless of intake. If the sodium chloride intake is limited to less than 1.5 gm a day, little fluid will be retained. When the

*Adverse reactions that may have been associated with albumin administration were encountered in 10 patients, a third of the series reported by Faloon et al.⁴¹ Directly related to the albumin injections were 2 cases of acute pulmonary edema, 1 fatal 1 of chill and fever followed by coma and death 1 of fatal nosebleed and a fatal esophageal hemorrhage. One patient bled on two occasions from a gastric ulcer soon after albumin injections. Two other patients bled from ruptured esophageal varices four and seven days after albumin therapy had been stopped both died. Two patients developed pleural effusions. It was difficult to ascertain how directly the albumin therapy contributed to these deaths. However, it is apparent that such therapy may not be without danger and should be used with caution.

gical procedures as injection of the esophageal collateral veins,^{24, 25} mediastinotomy²⁶ and gastrectomy²⁷ and the various operations for shunting blood from the portal to the systemic circulation²⁸⁻³⁰ are appearing in increasing numbers. Positive criteria indicating the procedure of choice are not yet available. Many more operations and controlled studies are necessary.

The results of A. H. Blakemore,³¹ who has had a large experience in the shunting operations, are illustrated in Table 2. He has tried one of several shunting procedures on 43 patients with cirrhosis with a decreasing operative mortality and an in-

have achieved good results with this operation. Optimal nutritional therapy was not usually possible after the patients left the hospital, and some of the operations were done in a rush of enthusiasm before the patients had been adequately prepared. However, patients who are abstemious and well treated by diet frequently have spontaneous remissions. The poor end results and high postoperative mortality of the patients in this series of "button" operations raise grave doubts of its value. It may be that the modification recently described by Lord³⁵ will prolong the period of relief

TABLE 2 *Results of Blood-Shunting Operations for the Relief of Ascites and Bleeding Varices in Cirrhosis of the Liver **

PURPOSE OF OPERATION	NO OF CASES	POSTOPERATIVE DEATHS	PATIENTS SURVIVING 1 YEAR OR MORE WITHOUT RECURRENCE	TOTAL DEATHS OVER 3 YEARS	RECURRENCE OF BLEEDING (MILD)	DISAPPEARANCE OF ASCITES
Ascites	6	2	2	14 (38%)	2	3
Hemorrhage†	37	7 (19%)	12 (32%)	14 (38%)	2	3

*Based on personal communication from A. H. Blakemore of New York City.

†Three patients also had ascites.

creasing number of the anastomoses remaining patent. But the operation is formidable and should probably be undertaken only in patients in the best of condition. Again, this large series is still too small and the patients not followed long enough for final conclusions to be drawn.

Two years ago Crosby and Cooney³² described what appeared to be an ideal surgical method for the relief of intractable ascites. A modified Murphy button was inserted into the abdominal wall connecting the peritoneal cavity with the subcutaneous tissues, resulting in a constant emptying of ascitic fluid into the subcutaneous space whence it was returned to the circulation. The series was small, but the results were good. In contrast, the results of this procedure performed on 14 service patients from the Boston City Hospital and the Mount Auburn Hospital, Cambridge, have been poor.³³ Five patients died in the postoperative period, 6 in from three weeks to one year and 2 in from one to two years after the operation, 1 is surviving three years after operation. Of the 9 who survived the postoperative period, 4 had a recurrence of ascites within one month, 3 within three months, and 1 within fourteen months. No functioning buttons were found in the 9 autopsied patients: 4 were plugged with fibrin, and 3 with omentum, and in 5 a pseudoperitoneal cavity similar to that recently described in detail by Welch³⁴ had formed. Only 4 of the 14 patients were definitely improved for appreciable lengths of time.

It should be pointed out that this series of patients, under service rather than private care, is not directly comparable with those of others who

from ascites. No other reports of this procedure have appeared.

Recently, two significant developments have been added to the medical treatment of intractable ascites: the intravenous administration of concentrated human serum albumin, and the provision of diets low in salt. Janeway and his associates³⁵ and Thorn et al.³⁷ observed that albumin injections in doses large enough to raise the serum albumin concentration to normal induced little more than a transient diuresis. Patek and his co-workers³⁸ confirmed this in a short-term experiment. But Kunkel et al.³⁹ reported the complete disappearance of ascites in 14 of 15 patients given albumin intravenously. As might be expected, those with early ascites and generalized edema responded more readily than patients with long-standing ascites and other evidences of excessive portal obstruction.

In an effort to elucidate the reasons for these discrepancies and the mechanisms responsible for the formation and disappearance of ascites in cirrhosis, Faloon and his associates⁴⁰ studied 29 patients with ascites treated with intravenous albumin, some over long periods. Four patients had a diuresis that began soon after the first albumin administration, 7 had a delayed response, and 3 responded only after the salt content of the diet had been reduced. There were 6 failures — 6 patients who did not respond although their serum albumin concentration was maintained at between 3 and 4 gm per 100 cc for long periods. The results in 9 patients were classified as indeterminate because the pa-

tients were neither treated nor followed long enough *

Responses just as erratic as those after albumin administration have been seen in patients treated with diet alone and in those given mercurial diuretics. In an effort to find a common metabolic defect altered in patients showing a response to these several measures, sodium-balance studies were performed by Faloon et al.⁴¹ The patients with decompensated cirrhosis were found to be unable to excrete administered sodium except in very small amounts. When diuresis occurred,

but with 6 gm of sodium chloride given in addition. He remained in positive sodium and water balance, gained 12 pounds in weight and required an average of 20 gm of albumin a day to maintain a normal serum albumin concentration. On withdrawal of the added 6 gm of salt his sodium balance became negative, and he stopped gaining weight and required daily only 11 gm of albumin to maintain the same serum albumin concentration.

The mechanism of this inability to excrete sodium is obscure, but the therapeutic implications are obvious. The frequency of abdominal paracentesis

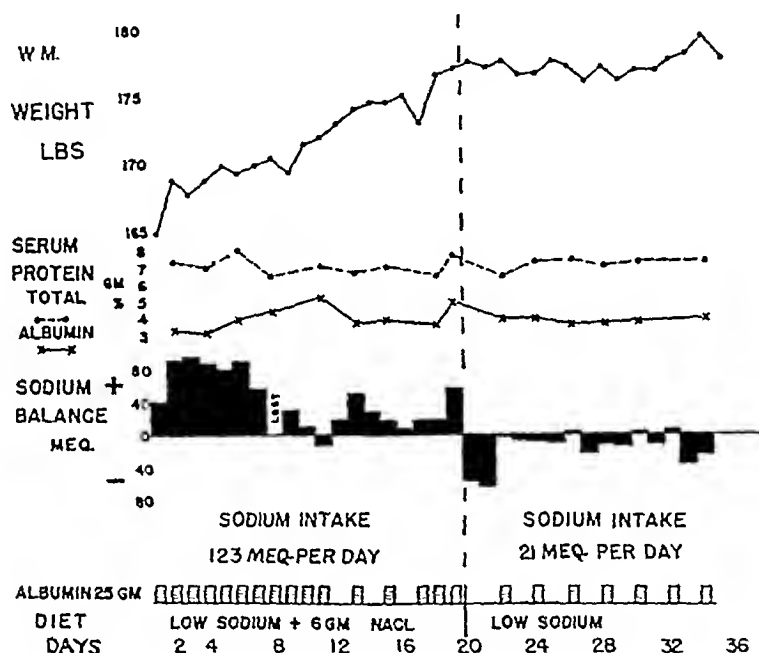

FIGURE 5 The Effect of Sodium Restriction in the Diet of a Patient Who Is Accumulating Ascites

The serum albumin level had previously been raised to normal by intravenous concentrated salt-poor human albumin. This was continued at a rate necessary to maintain the serum albumin at a normal level.

whether spontaneous or accompanying albumin or mercurial administration, urinary sodium rose markedly and a negative sodium balance ensued.

Figure 5 illustrates the effect of withholding salt from the diet of a patient who had required frequent paracenteses in spite of a serum protein concentration maintained at normal by the intravenous administration of albumin. Over a twenty-day period he was provided with a low-sodium diet, containing about 1.25 gm of sodium chloride a day,

can be reduced if the patient is maintained on a low-sodium diet supplemented, if desired, by ammonium chloride and mercurial diuretics. intake is 6 gm, as in the ordinary hospital diet without added salt, around 500 cc may be retained When the intake is 10 gm, as in the usual American diet salted to taste, approximately a liter of fluid, equal to 2 pounds of body weight, may be retained a day

Patients with ascites have not generally been treated with a low-salt diet in the past because it is difficult to prepare a nutritious diet, particularly one adequate in protein, which is at the same time low in salt The diet employed by Faloon et al, presented in Table 3, contains only approximately

There is general agreement that it is one of the most important therapeutic measures, as pointed out by Jones and Volwiler⁴⁴ in their review of the treatment of chronic hepatitis This clinical observation is supported by the experimental work of Bradley⁴⁵ on the relation of posture to hepatic blood flow

SUMMARY

The employment of a palatable, nutritious diet adequate in protein and not reduced in fat content

TABLE 3 Nutritious Diet Low in Sodium *

Food	Amount	Household Measures	Carbohydrate gm	Protein gm	Fat gm	Sodium mg
Breakfast

*This diet which was compiled by Miss Kathleen A. Chotow dietitian at the Thorndike Memorial Laboratory, contains approximately 3000 calories and 330 mg of sodium or 835 mg of sodium chloride. Caloric values were calculated from standard food tables. Sodium values were taken from Sodium and Potassium Analyses of Foods and Waters (fifth list), Mead Johnson and Company, Evansville, Indiana, and The Chemical Composition of Foods (second edition) by R. A. McCance and E. M. Widdowson (Brooklyn: Chemical Publishing Co. 1947).

Fresh fruits and vegetables should be used. Butter must be sweet or washed. Bread must be salt poor and may be obtained at some bakeries or made at home with salt poor flour and low sodium milk powder instead of whole milk. Cottage cheese is the only cheese allowed but should be washed. Processed, canned or smoked meats should not be used. Low-sodium milk powder (Looalac) may be obtained from Mead Johnson & Company. Cereals allowed: Farina, plain; Wheatena; Instant Ralston Maltex; Oatmeal (rolled oats); Puffed Rice; Puffed Wheat; and Shredded Wheat. Many quick-cooking cereals and dry cereals are high in salt.

0.8 gm of sodium chloride, but there are 131 gm of protein, 309 gm of carbohydrate and 143 gm of fat—approximately 3000 calories. The salt content is kept low by the use of bread of low-salt content, sweet butter, vegetables cooked or canned without added salt and a low-sodium milk powder, or other low-sodium protein supplement. The taste of the diet may be improved by the employment of a salt substitute—one in which the sodium, not the chloride ion, is replaced. No untoward symptoms due to sodium or chloride deprivation were noted in this study, which was performed in the winter months, but such symptoms might develop during the hot summer months in patients being maintained free of ascites on a low-salt diet. Finally, the importance of bed rest in the treatment of chronic hepatic disease should be mentioned

has, with chemotherapy and blood transfusions, improved the prognosis of hepatic cirrhosis. Such nutrients as vitamins, methionine and choline are probably supplied in adequate amounts by the nutritious diet described. If food cannot be taken in a sufficient quantity, crude food complements should be administered. The role of surgery in the treatment of portal hypertension is still not established, but it seems probable that the mortality from ruptured esophageal varices may be reduced by procedures such as portal-systemic venous anastomosis. Intractable ascites is best treated by a nutritious diet, low in salt, supplemented by mercurial and other diuretics and, if necessary, by intravenously administered, salt-poor, concentrated serum albumin.

VARIATIONS IN HEPATIC BLOOD FLOW IN MAN DURING HEALTH AND DISEASE*

STANLEY E. BRADLEY, M.D.†

NEW YORK CITY

THE liver acts as a selective barrier between the gastrointestinal tract and the systemic circulation, metabolizing, detoxifying and elaborating for further physiologic disposition various substances that enter the portal blood during digestion. Unquestionably, the rich and complex vasculature of the liver serves these processes by providing an adequate supply of oxygen and raw materials. In

of data obtained under these circumstances and prevent quantitative evaluation of discrete parenchymal activities.

The recent development of methods for the atraumatic catheterization of the great veins by Cournand and his co-workers¹ at Bellevue Hospital has provided a means by which hepatic venous blood may be sampled at frequent intervals in human subjects without difficulty. By this method a long, radio-opaque ureteral catheter may be inserted into an antecubital vein, and passed under fluoroscopic control through the superior vena cava and right atrium into the inferior vena cava and thence into one of the right hepatic veins (Fig 1). Blood may then be withdrawn through the catheter as desired. A vast new field of study has thus been opened to exploration. The hepatic extraction of various substances may be measured directly, and hepatic blood flow may be estimated by a clearance technic.² Bromsulfalein (BSP) has been used for the latter purpose since it is removed from the blood almost exclusively by the liver.³ Hence it seems reasonable to assume that the rate of intravenous infusion of BSP is equal to the rate of hepatic BSP removal when the BSP concentration in the blood is kept constant. Dividing the calculated rate of removal by the difference between BSP concentrations in hepatic venous and peripheral arterial (or venous) blood will yield a value approximating hepatic blood flow. The principle of this procedure is familiar as the basis of the methods by which cardiac output and renal blood flow are measured. Since the dye may be removed to a certain extent by tissues outside the liver, since the concentration in peripheral arterial blood may not equal the concentration in the portal vein, and since the blood coming from only one hepatic vein is sampled and may not therefore be representative of the liver as a whole, the figure for hepatic blood flow has been referred to as "estimated hepatic blood flow" (EHBf). However, values given by this method are in agreement with those obtained by other procedures⁴ not open to these particular errors and may be considered valid measures of the hepatic circulation. It is evident, however, that EHBf is a measure of volume of blood flowing into the splanchnic vasculature each minute, without reference to the relative contributions of the mesenteric, splenic, gastric and hepatic arterial inflows.

In 50 normal resting human subjects studied at the Evans Memorial Hospital in Boston, EHBf ranged from 950 to 1840 cc per minute per 1.73 M² of body surface, averaging 1490 cc per minute

FIGURE 1 Catheterization of the Hepatic Veins

In this skiagraph, the radio-opaque catheter may be seen passing through the right axillary and subclavian veins to the superior vena cava and thence through the right atrium and upper portion of the inferior vena cava to a vein in the right lobe of the liver.

addition, this extensive vascularity itself may indicate an important role in cardiovascular dynamics.

Unfortunately, very little is known about the physiology of the hepatic circulation, largely because it is so inaccessible. Traumatic surgical manipulations required for its study are obviously inapplicable in the study of man and are open to serious question when used in the study of animals. Gross distortions of function arising from operative injury and anesthesia complicate the interpretation

*From the Department of Medicine, Columbia University College of Physicians and Surgeons, and the Presbyterian Hospital.

†Assistant professor of medicine, Columbia University College of Physicians and Surgeons; assistant attending physician, Presbyterian Hospital.

Thus, approximately 25 per cent of the basal cardiac output appears to pass through the splanchnic circuit. The kidneys and the brain also receive large amounts of blood, approximately 1200 cc passing through the kidneys⁵ and 800 cc through the brain,⁶ on the average, each minute. Since the cerebral circulation must be kept constant within relatively narrow limits it is obvious that the major task of vascular regulation must fall upon the liver and kidneys. Numerous studies⁷⁻¹⁰ have demonstrated conclusively that the renal blood flow is highly variable and quickly adjusted to current requirements in such a manner as to maintain arterial pressure and to compensate for relatively inadequate responses of cardiac output as in chronic anemia or orthostasis. Indeed, this activity may be carried to such an extreme that irreversible renal damage may occur after prolonged intrarenal vasoconstriction during shock. Studies of the hepatic circulation indicate that the liver also plays a prominent role in vascular homeostasis.

In animal experiments, a remarkable variation in hepatic blood flow has been observed, ranging in one study¹¹ from 40 to 160 cc per minute per 100 gm of liver tissue. The variability has been attributed to irregularity of blood flow through the sinusoids. Direct observation of the transilluminated liver has revealed free flow of blood through only about a quarter of the sinusoids at any moment, owing to intermittent passage through individual vessels.¹² With hyperemia, a larger number of sinusoids open to permit passage of a correspondingly larger volume of blood, whereas during hepatic ischemia intermittency becomes more marked. In human subjects the range of blood flow was relatively large, but it was by no means of this magnitude and appeared indeed chiefly a function of the errors inherent in the method of measurement. Moreover, the values for BSP extraction by different parts of the liver agreed fairly closely. Hence it appears that blood is distributed evenly throughout the liver and that changes in blood flow may be attributed to diffuse rather than to gross focal alterations in vasomotor activity. Of course, it is impossible to say whether vasomotor activity responsible for changes in EHBF also affects the splanchnic arterioles, but it seems wholly likely that it does, since vasoconstriction in the liver alone would operate to impound blood in the portal area with detrimental effect upon systemic hemodynamics. Exclusively hepatic vasodilation would produce the same effect by raising the pressure in the hepatic arterial capillaries, with a resulting dynamic obstruction to portal venous outflow.

A study of hepatic circulatory dynamics during exercise was undertaken in collaboration with Dr E. DeF. Baldwin at the Columbia-Presbyterian Medical Center for the purpose of assessing integration of the hepatic circulation into the total circulatory system during stress. Simultaneous measure-

ments of cardiac output (by the direct Fick method), renal blood flow (by the sodium p-amino hippurate clearance) and hepatic blood flow (by BSP clearance) were made in normal volunteers prior to and during exercise, which consisted of bicycling against weights in the recumbent position. The findings during such a study are presented in Figure 2. Blood-pressure recordings, measured in another person under similar circumstances, have been inserted in Figure 2 to provide a complete

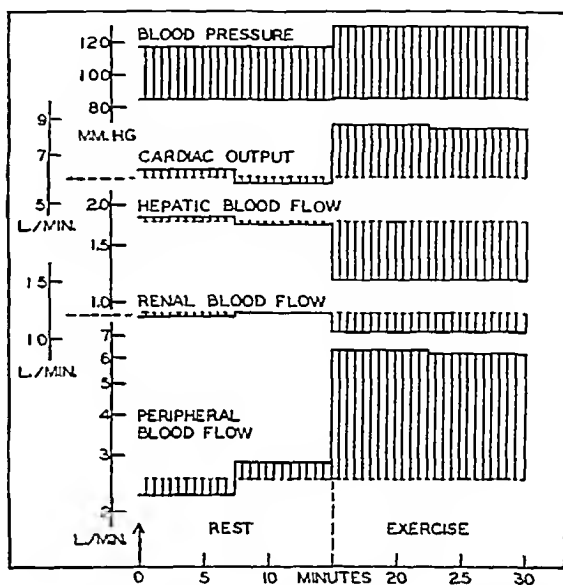

FIGURE 2 Effect of Exercise on Estimated Hepatic Blood Flow, Renal Blood Flow, Peripheral Blood Flow and Arterial Pressure in Man

With the exception of the arterial pressure, which was measured sphygmomanometrically in a separate study, all determinations were made as nearly simultaneously as possible under standard conditions. The sum of the values for estimated hepatic blood flow (bromsulfalein method) and effective renal blood flow (sodium p-aminohippurate clearance corrected for the hematocrit) was subtracted from the cardiac output (direct Fick method) to obtain a figure for peripheral blood flow. Exercise (bicycling against weights in recumbency) was started thirty minutes after the beginning of the study. Cardiac output increased, but blood flow through the renal and hepatoportal circuits fell, thus permitting a considerably larger increment in blood flow to the periphery than would have been possible on the basis of the change in cardiac output alone.

picture of hemodynamic events. Although little change in blood pressure occurred during exercise the output of the heart almost doubled. At the same time the blood flow through the kidney and the liver (that is, the splanchnic vascular bed) fell sharply, the hepatic blood flow to a much greater extent than the renal. The blood flow to other circuits — the brain, heart and especially the muscles — thus increased to a greater extent than is indicated by the change in cardiac output. In this way blood was made available at the expense of the liver and kidneys, while the heart was spared

THE liver acts as a selective barrier between the gastrointestinal tract and the systemic circulation, metabolizing, detoxifying and elaborating for further physiologic disposition various substances that enter the portal blood during digestion. Unquestionably, the rich and complex vasculature of the liver serves these processes by providing an adequate supply of oxygen and raw materials. In

of data obtained under these circumstances and prevent quantitative evaluation of discrete parenchymal activities.

The recent development of methods for the atraumatic catheterization of the great veins by Cournand and his co-workers¹ at Bellevue Hospital has provided a means by which hepatic venous blood may be sampled at frequent intervals in human subjects without difficulty. By this method a long, radio-opaque ureteral catheter may be inserted into an antecubital vein, and passed under fluoroscopic control through the superior vena cava and right atrium into the inferior vena cava and thence into one of the right hepatic veins (Fig. 1). Blood may then be withdrawn through the catheter as desired. A vast new field of study has thus been opened to exploration. The hepatic extraction of various substances may be measured directly, and hepatic blood flow may be estimated by a clearance technic.² Bromsulfalein (BSP) has been used for the latter purpose since it is removed from the blood almost exclusively by the liver.³ Hence it seems reasonable to assume that the rate of intravenous infusion of BSP is equal to the rate of hepatic BSP removal when the BSP concentration in the blood is kept constant. Dividing the calculated rate of removal by the difference between BSP concentrations in hepatic venous and peripheral arterial (or venous) blood will yield a value approximating hepatic blood flow. The principle of this procedure is familiar as the basis of the methods by which cardiac output and renal blood flow are measured. Since the dye may be removed to a certain extent by tissues outside the liver, since the concentration in peripheral arterial blood may not equal the concentration in the portal vein, and since the blood coming from only one hepatic vein is sampled and may not therefore be representative of the liver as a whole, the figure for hepatic blood flow has been referred to as "estimated hepatic blood flow" (EHBf). However, values given by this method are in agreement with those obtained by other procedures⁴ not open to these particular errors and may be considered valid measures of the hepatic circulation. It is evident, however, that EHBf is a measure of volume of blood flowing into the splanchnic vasculature each minute, without reference to the relative contributions of the mesenteric, splenic, gastric and hepatic arterial inflows.

In 50 normal resting human subjects studied at the Evans Memorial Hospital in Boston, EHBf ranged from 950 to 1840 cc per minute per 1.73 M² of body surface, averaging 1490 cc per minute

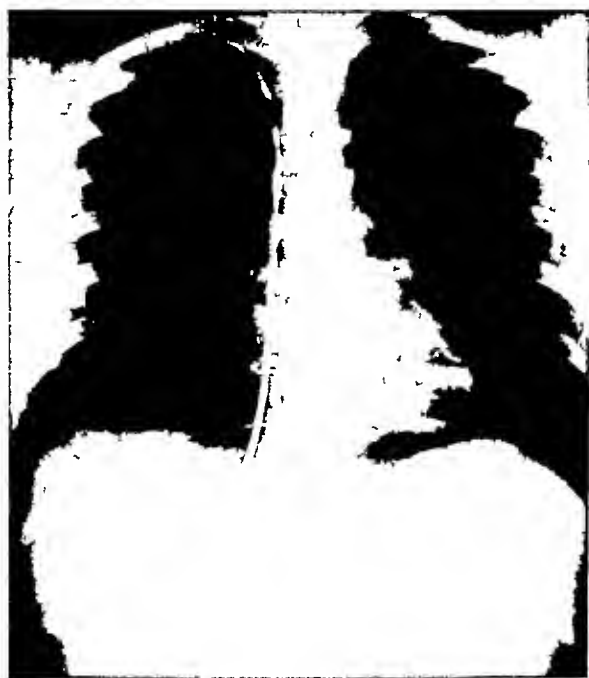

FIGURE 1 Catheterization of the Hepatic Veins

In this skiagraph, the radio-opaque catheter may be seen passing through the right axillary and subclavian veins to the superior vena cava and thence through the right atrium and upper portion of the inferior vena cava to a vein in the right lobe of the liver.

addition, this extensive vascularity itself may indicate an important role in cardiovascular dynamics.

Unfortunately, very little is known about the physiology of the hepatic circulation, largely because it is so inaccessible. Traumatic surgical manipulations required for its study are obviously inapplicable in the study of man and are open to serious question when used in the study of animals. Gross distortions of function arising from operative injury and anesthesia complicate the interpretation

*From the Department of Medicine, Columbia University College of Physicians and Surgeons, and the Presbyterian Hospital.

†Assistant professor of medicine, Columbia University College of Physicians and Surgeons; assistant attending physician, Presbyterian Hospital.

demonstrable for a period of at least twenty-four hours after the onset of the reaction. It is not so well known, perhaps, that pyrogen may have such an effect even when fever does not develop. In a clinical investigation of this factor¹⁷ typhoid vaccine was administered to patients undergoing fever therapy, after premedication with aminopyrine. As a result, the body temperature remained unchanged, but the physiologic response was otherwise unaltered. In 2 of 8 subjects, slight tender enlargement of the liver was demonstrable, there was an increase in serum alkaline phosphatase, and the cephalin-cholesterol flocculation test became positive, reverting to normal in a few days. In these subjects the detrimental effect of the pyrogenic

Beautiful plastic reconstructions have been made by the introduction of an injection mass of celloidin, neoprene or other materials under pressure into the hepatic artery and portal veins, permitting it to harden and then carefully digesting away the parenchymal tissue, as demonstrated by McIndoe.¹⁸ These models show in a most convincing and graphic manner how Laennec's cirrhosis affects the blood

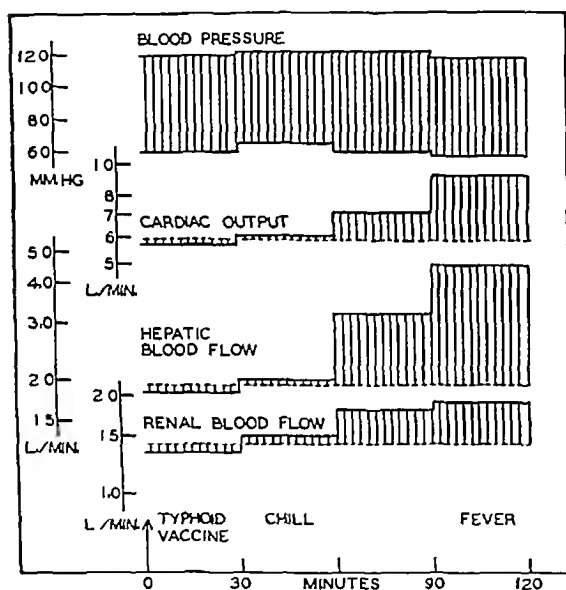

FIGURE 4 Effect of the Pyrogenic Reaction upon Arterial Pressure, Cardiac Output, Estimated Hepatic Blood Flow and Renal Blood Flow in Man

Results from two studies, one in which hepatic blood flow was determined after intravenous administration of typhoid vaccine (100 000,000 organisms) and a second in which arterial pressure, cardiac output (ballistocardiograph) and renal blood flow were measured after a dose of pyrogenic inulin (100 mg intravenously) are combined in this graph. For the sake of convenience the pyrogen is noted here only as "typhoid vaccine". During pyrexia, hepatic hyperemia develops in association with renal hyperemia as the cardiac output increases.

substance was evident despite the absence of fever. It is a very short step indeed to the inference that similar reactions with or without fever would be undesirable — perhaps even disastrous — during convalescence from inflammatory hepatic disease.

Disturbances of hepatic blood flow may be expected to result from the structural disorganization following severe injury by toxic agents or infection. Cirrhosis, in particular, is associated with a striking deformation of the hepatic blood vessels

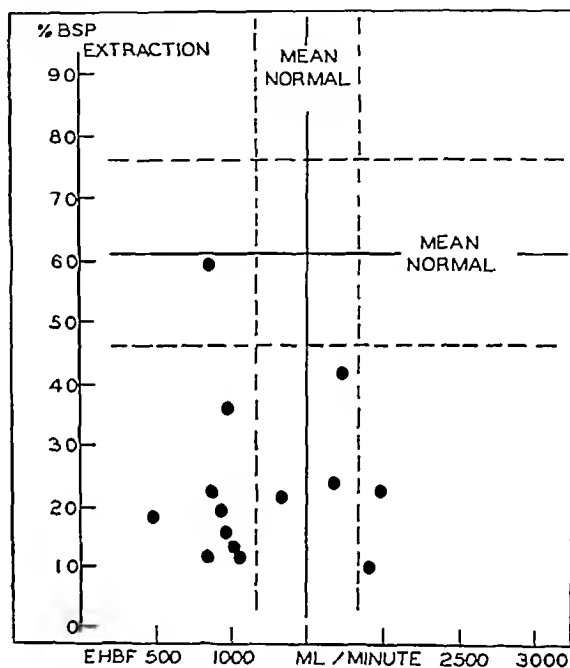

FIGURE 5 Estimated Hepatic Blood Flow (EHBF) and Bromsulfalein (BSP) Excretion in Cirrhosis of the Liver

vessels of the liver. One can see at a glance the simplification, reduction and distortion of both arterial and portal venous radicles, in sharp contrast to the complex and massive arrangement of the innumerable interwoven vessels of the normal. On anatomic grounds alone one would almost certainly say that hepatic blood flow is reduced. Nonetheless, in the absence of supporting functional evidence, the question has remained open since vasodilation or shunting, even in such a circulatory bed as this, might result in hyperemia. Indeed, evidence has been brought forward in support of the claim that the hepatic outflow may be augmented, rather than reduced, perhaps chiefly as a result of enhanced arterial inflow, which may impose a dynamic resistance to portal venous inflow and contribute to the elevation of portal pressure. Thus, in 1907 Herrick¹⁹ found that the hepatic artery may be perfused with saline solution in the liver removed after death, more easily in the cirrhotic than in the normal person. And Dock,²⁰ more recently, has found decreased arterial resistance to

the effort required to expel sufficient blood to meet the total need imposed by exercising muscle

The subjects of this investigation were placed under the stress of exercise alone as far as it was possible. Hence they were maintained in the recumbent position throughout. The upright position imposes an independent burden upon the circulation and if coupled with exercise might

right position (with the use of a tilt-table) are compared with figures for cardiac output (obtained by Dr André Cournand) and renal blood flow (taken from figures published by H W Smith⁷) determined in other normal subjects under similar conditions. It is evident that the hepatic and renal hemodynamic adjustments were similar to those observed in response to exercise, whereas cardiac output was reduced by gravitational interference with the return of blood to the heart. Hence, the hepatic and splanchnic vasoconstriction implicit in the reduction of blood flow in spite of an elevated mean arterial pressure operate to maintain blood flow to areas more sensitive to the effects of ischemia.

What bearing may these findings have upon understanding of disease of the liver? Obviously, any attempt to answer this question enters the realm of speculation. The only conclusions we are entitled to draw from these observations relate exclusively to normal man and throw light only upon normal regulatory mechanisms. Nonetheless, the temptation is irresistible, and with this warning it is perhaps permissible to make certain tentative inferences. There is growing agreement that convalescence from inflammatory hepatic disease and, in particular, from infectious hepatitis is disturbed by early mobilization and return to activity.^{11, 13} Since an adequate supply of blood is usually essential in hastening and maintaining the repair of damaged tissue, and since ordinary activity involves exertion in the upright position, it is possible that the vasoconstriction demonstrable in these studies is one of the factors involved in causing relapse and retarding recovery.

Another factor that comes to mind in such speculations is the possible influence of minor febrile infections. Fever has been shown¹⁶ to produce a striking physiologic disturbance that affects nearly every organ system in the body. The response of the cardiovascular system during pyrogenic reactions is particularly striking, and it is not surprising therefore to find that the hepatic vasculature participates actively in these readjustments.

A composite picture of the typical circulatory events observed during the pyrogenic reaction in 2 normal subjects is presented in Figure 4. Hepatic blood flow was determined in 1, and cardiac output, arterial pressure and renal blood flow in the other. The marked increase in vascular activity is clearly evident. Cardiac output increased after the chill phase in association with increased blood flow through both kidney and liver. The increment in cardiac output appears to be accounted for in large part by the augmentation in renal and hepatic blood flow. Of considerable interest is the appearance of hepatocellular dysfunction, which was evident in the marked depression of the extraction of BSP from the blood perfusing the liver. Brom-sulfalein was no longer efficiently eliminated from the blood by the liver, and retention of BSP was

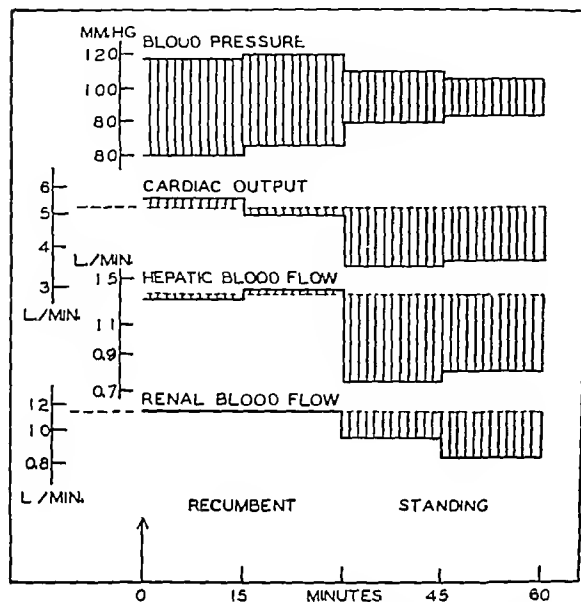

FIGURE 3 Effect of Standing Upright upon Arterial Pressure, Cardiac Output, Estimated Hepatic Blood Flow and Renal Blood Flow in Man

This composite picture of the vascular readjustments after a change in position from recumbency to standing by means of a tilt-table is based upon figures for arterial pressure (Hamilton manometer) and estimated hepatic blood flow determined simultaneously in one patient and for cardiac output (provided through the courtesy of Dr André Cournand) and renal blood flow (Chasis et al.⁷) obtained in other patients under similar conditions. Since cardiac output was not measured at the same time as renal and hepatic blood flow, the peripheral blood flow could not be calculated. With the postural change there was a fall in cardiac output without much change in mean arterial pressure although the pulse pressure decreased, apparently as a result of diminished stroke volume. Vasoconstriction in the hepatoportal and renal vascular beds apparently contributes to the increased total peripheral vascular resistance implicit in this phenomenon, thus accounting for the reduction in local flows despite maintenance of arterial pressure.

be expected to influence the picture and make interpretation difficult. It seemed of great interest to know whether standing alters the hepatic circulation as much as it affects the total circulation, and so a study of the question was undertaken at the Evans Memorial Hospital in Boston.¹³ These workers have investigated the question very thoroughly, and there is little reason to doubt the accuracy of the synthesis presented here. In Figure 3, arterial pressure measured with the Hamilton membrane manometer and hepatic blood flow determined before and after assumption of the up-

There is little doubt that this obstruction is largely responsible for the elevation in the portal venous pressure, and for the sequelae of that portentous development.

In this discussion an attempt has been made to indicate an approach to the detailed analysis of hepatic function and dysfunction in man. On the basis of the studies described here and those of many other workers one can assign to the liver a role of importance not only in metabolic activities but also in cardiovascular dynamics, since it provides, with the kidney, a kind of hemodynamic buffer against undue stress. Although the implications of this concept are not yet completely explored, it is evident that the hepatoportal circulation has become a matter of more than passing interest to students of cardiovascular physiology and disease.

POST-PARTUM HEMATOMA*

ARTHUR W LYONS, M.D.†

LAWRENCE, MASSACHUSETTS

IN REVIEWING discussions on intra-partum and post-partum complications in the obstetric textbooks one finds little space allotted to hematomas. A survey of the literature discloses 188 cases of paravaginal hematoma reported from 1554 to 1948. The incidence varies from 1/1951 deliveries reported by Moschkow¹ to 1/7000 by De Lee². The immediate vulvar type is the most common. In a review of 1250 deliveries 3 cases of hematoma were found: the first was vulvar, requiring removal of episiotomy sutures, evacuation of the clot and resuturing two hours after delivery; the second was vulvar, requiring removal of sutures, evacuation of the clot and resuture twenty-four hours after delivery; and the third, which was of the late paravaginal type, is reported below. Another group that has been separately reported is the retroperitoneal. Williams³ reviewed 33 cases of this kind, 22 occurring prior to 1880, with a mortality of 73

per cent. De Lee² states that the mortality in this type was 40 per cent prior to the institution of active treatment. Hamilton⁴ reported a mortality of 83 per cent since the introduction of active treatment, and Frank-Kamenetsky⁵ one of 93 per cent.

Obstetric hematomas, then, may be vulvar, paravaginal, intraligamentary or retroperitoneal, or a combination of these locations. The vulvar type appears immediately or within a few hours after delivery, the bleeding vessel being located external to the pelvic fascia and levators. Later, a blue, sensitive, elastic mass appears, and the diagnosis is made on inspection and palpation. The paravaginal type may be unnoticed for some time. The patient complains of increasingly severe pain, "bearing-down" pains or rectal discomfort. On examination a mass may be found in the vaginal wall projecting into the vagina. On rectal examination a mass may be palpated. This is the type that can dissect upward beneath Poupert's ligament, into the broad ligament, and retroperitoneally to the diaphragm. Finally, with massive hemorrhage,

perfusion with kerosene in alcoholic cirrhosis, but not in other types of the disorder. Obviously, such post-mortem changes may have no bearing on events during life. Hence, in collaboration with Dr F J Ingelfinger, in Boston, and Drs A E Groff and G P Bradley, in New York, hepatic blood flow was estimated in a group of patients with well established Laennec's cirrhosis and chronic alcoholism, and in 3 persons with cirrhosis due to periportal fibrosis, schistosomiasis and syphilis, respectively.²¹ The results of this study are summarized in Figure 5, from which values obtained in patients who ex-

is particularly interesting. It may indicate arteriovenous shunting, perfusion of a large mass of non-extracting scar tissue or failure of damaged parenchymal cells to remove the dye from blood passing through the liver. Studies of hepatic oxygen excretion were made to assess the relative importance of these possibilities.

In Figure 6, the values for hepatic oxygen arteriovenous concentration differences are plotted against those for hepatic venous oxygen saturation in normal subjects and patients with cirrhosis. It may be seen that, with one exception, the hepatic oxygen arteriovenous difference in cirrhotic patients exceeded the normal range, and in most cases there was evidence of increased hepatic venous unsaturation. However, splanchnic oxygen consumption did not increase, for the increment in hepatic oxygen arteriovenous difference usually failed even to compensate for the reduction in blood flow, so that oxygen consumption tended to fall. These changes would be expected to follow a reduction in the mass of operative parenchymal tissue associated with maintenance of oxygen consumption per unit mass of residual tissue, at a relatively constant level. In the kidney, the oxygen arteriovenous difference tends to remain within narrow limits despite wide fluctuations in blood flow, indicating variation of oxygen consumption by renal tissue as a function of blood flow. The liver appears to differ radically from the kidney in this respect since oxygen excretion rises when blood flow through the liver is decreased during standing,^{22, 23} and it therefore seems reasonable to ascribe increased hepatoportal oxygen excretion during cirrhosis to a more sluggish flow of blood through active tissues. Continued normal oxygen uptake by the intestines and spleen from a smaller volume of blood may account in part for the change in hepatic arteriovenous difference. But the portal arteriovenous oxygen difference is small (0.93 vol per cent in each of 2 patients with cirrhosis and portal hypertension at operation), and the hepatic arteriovenous difference may be high in cirrhosis after ligation of the portal vein.²⁴ It may be inferred, therefore, that hepatic tissue is the most important site of oxygen uptake and that augmented oxygen excretion indicates relative ischemia of hepatic parenchyma. Hence, it appears on functional grounds that hepatic flow is greatly reduced in cirrhosis of the liver, regardless of etiology, as a result of an increased vascular resistance that acts to produce a relative ischemia of hepatic tissues, in which excretive—that is, parenchymal—cells figure much less prominently than in the normal organ. These observations are consistent with the view that fibrotic contraction impedes the flow of blood through the liver and that parenchymal injury thus has primacy in production of the structural changes of cirrhosis. Nonetheless, it is likely that the obstruction to blood flow may perpetuate and exaggerate the fundamental lesion

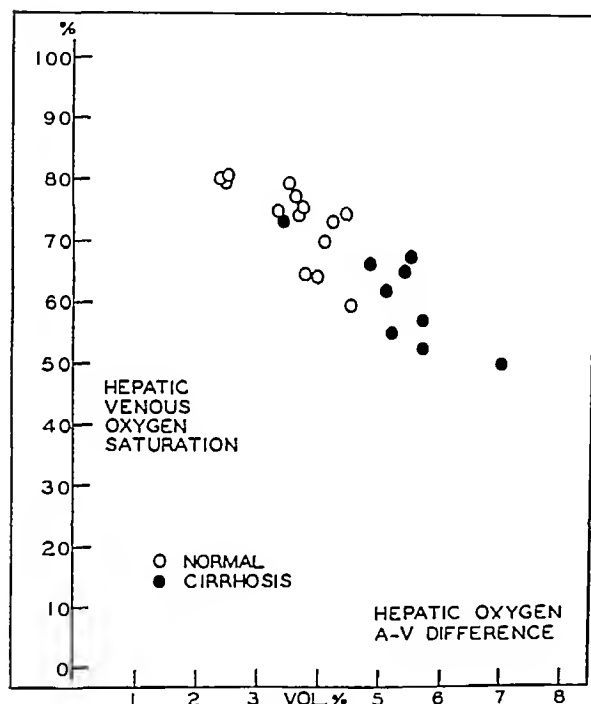

FIGURE 6 Hepatic Oxygen Arteriovenous Difference and Hepatic Venous Oxygen Saturation in Cirrhosis of the Liver. With one exception the values for hepatic oxygen arteriovenous difference were depressed in cirrhosis (closed circles) below the normal values (open circles). There was an associated but less striking reduction in hepatic venous oxygen saturation.

creted less than 10 per cent of BSP have been excluded. In only 4 subjects did the value for blood flow exceed the normal mean value of EHBf.

In 9, EHBf fell below the lowest normal figure. It should be noted that the values for hepatic blood flow are subject to error as result of the marked depression in the ability of the liver to remove BSP in all but 1 member of this series. Such an error would result in falsely high values for EHBf since the removal of BSP by extrahepatic tissues would contribute disproportionately to the total calculated removal rate. Hence the low values actually observed are the more significant of a true reduction in blood flow. The reduction in BSP excretion

There is little doubt that this obstruction is largely responsible for the elevation in the portal venous pressure, and for the sequelae of that portentous development

In this discussion an attempt has been made to indicate an approach to the detailed analysis of hepatic function and dysfunction in man. On the basis of the studies described here and those of many other workers one can assign to the liver a role of importance not only in metabolic activities but also in cardiovascular dynamics, since it provides, with the kidney, a kind of hemodynamic buffer against undue stress. Although the implications of this concept are not yet completely explored, it is evident that the hepatoportal circulation has become a matter of more than passing interest to students of cardiovascular physiology and disease.

POST-PARTUM HEMATOMA*

ARTHUR W LYONS, M.D.†

LAWRENCE, MASSACHUSETTS

IN REVIEWING discussions on intra-partum and post-partum complications in the obstetric textbooks one finds little space allotted to hematomas. A survey of the literature discloses 188 cases of paravaginal hematoma reported from 1554 to 1948. The incidence varies from 1/1951 deliveries reported by Moschlow¹ to 1/7000 by De Lee.² The immediate vulvar type is the most common. In a review of 1250 deliveries 3 cases of hematoma were found: the first was vulvar, requiring removal of episiotomy sutures, evacuation of the clot and resuturing two hours after delivery; the second was vulvar, requiring removal of sutures, evacuation of the clot and resuture twenty-four hours after delivery; and the third, which was of the late paravaginal type, is reported below. Another group that has been separately reported is the retroperitoneal. Williams³ reviewed 33 cases of this kind, 22 occurring prior to 1880, with a mortality of 73

per cent. De Lee² states that the mortality in this type was 40 per cent prior to the institution of active treatment. Hamilton⁴ reported a mortality of 83 per cent since the introduction of active treatment, and Frank-Kamenetsky⁵ one of 95 per cent.

Obstetric hematomas, then, may be vulvar, paravaginal, intraligamentary or retroperitoneal, or a combination of these locations. The vulvar type appears immediately or within a few hours after delivery, the bleeding vessel being located external to the pelvic fascia and levators. Later, a blue, sensitive, elastic mass appears, and the diagnosis is made on inspection and palpation. The paravaginal type may be unnoticed for some time. The patient complains of increasingly severe pain, "bearing-down" pains or rectal discomfort. On examination a mass may be found in the vaginal wall projecting into the vagina. On rectal examination a mass may be palpated. This is the type that can dissect upward beneath Poupert's ligament, into the broad ligament, and retroperitoneally to the diaphragm. Finally, with massive hemorrhage,

*From the Obstetrical and Gynecological services, Bon Secours Hospital, Baltimore, Maryland.

†Staff member, St. John's Hospital, Lowell; staff member, Lawrence General and Clover Hill hospitals, Lawrence; formerly, chief resident in gynecology and obstetrics, Bon Secours Hospital, Baltimore, Maryland.

the patient exhibits signs of shock, necessitating immediate supportive measures

The etiology of this complication is quite apparent when one considers the progress of the fetus through the birth canal, subjecting the maternal tissue to long-standing contusing and avulsing trauma. And it is generally agreed that the immediate type is caused by trauma, which De Lee,² Hamilton⁴ and others list as the major causal factor. The late type is attributed to pressure necrosis of vessels caused by prolonged compression by the fetal head. Also listed as causes are laceration of inelastic vessels, toxemias, the presence of a blood dyscrasia and varicosities. Even slight trauma may activate these cases. Lacomme⁶ believes that hematomas may occur more frequently in the young primipara. The logic is apparent—the canal has not been previously dilated, and there is more tissue resistance. In general it may be said that the early hematomas are due to trauma and the late ones to pressure necrosis.

The diagnosis is made on the bluish discoloration, tumefaction and pain. Inspection and examination of any patient complaining of severe, continuous pain after delivery is mandatory. All reviewers stress the fact that cases are missed because the attending physician attributes the complaint of pain to episiotomy sutures. In the subperitoneal hematoma, tearing, labor-like pain continues, a high fundus is found, and early shock occurs.

Treatment should be prophylactic so far as possible. An episiotomy and the use of outlet forceps will help prevent vulvar damage, especially in young primiparas. A thorough inspection for tears and good tissue approximation are essential. Michaels and Herring⁷ stress the importance of the repair, stating that an insignificant ooze at the upper angle of a tear or an episiotomy may in a few hours be a large hematoma. Early diagnosis^{8, 9} and evaluation of the case is the next step. Expectant treatment is used when a small hematoma is discovered and does not increase under observation. A hematoma that is enlarging, or a hematoma that is large on discovery, should be incised and evacuated, and the bleeding controlled. This may be accomplished by suture, pressure, pack or hemostatic absorbable gauze, or a combination of these measures. If there has been severe hemorrhage, shock treatment is immediately instituted, blood replacement of course being most important. If infection is present, incision and drainage, culturing and the use of the most specific agent available are advisable. Immediate treatment with streptomycin and penicillin, while culture reports are awaited, seems a sensible plan.

In view of the early ambulation used in hospitals and the shorter hospitalization now popular, more late hematomas may be seen than in the past. The following case is presented with this consideration in mind.

CASE REPORT

A 28-year-old bipara, 7 days post partum, reported to the accident room complaining of severe perineal pain. The discomfort had begun with activity at home after discharge from the hospital. Pain had become so severe that she could not sit comfortably. There had been bright-red vaginal bleeding for 2 days, and the patient had become weak and light-headed. Her obstetrician stated that pregnancy and labor had been normal and that a median episiotomy had been done and a low forceps delivery effected without incident. The usual repair had been made. No lacerations had been observed, and no vulvoperineal mass or discoloration noted. The patient had apparently been in good condition on discharge.

The past history was noncontributory.

Physical examination revealed a hard, symmetrical mass extending about 10 cm above the pubis. The inguinal lymph nodes were enlarged bilaterally, more so on the left. On vaginal examination marked perineal blueness was found, extending beyond the ischial tuberosity left laterally and into the labium, and to the anal margin inferiorly. A gaping episiotomy incision exuded serosanguineous material from two openings, each about 2.5 cm in length. A moderate bloody vaginal discharge was present. Only one finger could be introduced into the vagina with comfort. A mass was found in the left wall about 7 cm inside the outlet, extending superiorly to the fornix and nearly obliterating the vaginal canal.

The temperature was 104.4°F, the pulse 140, and the respirations 22.

The urine showed a trace of albumin. The red-cell count was 2,860,000, with a hemoglobin of 58 per cent, and the white-cell count was not elevated, the blood chemical findings were normal. The blood type was O, and the patient was Rh+.

The diagnoses were late post-partum vulvovaginal hematoma, infected, median episiotomy, infected, and secondary anemia.

General treatment consisted of transfusion, intravenous administration of fluids, penicillin and streptomycin until the culture report revealed colon bacilli, and then streptomycin alone for 4 days.

Local treatment was definitive, incision and drainage of the mass being accomplished under sodium pentothal anesthesia. At this time about 500 cc. of blood clot and dark, thick blood with a strong odor of colon bacilli was evacuated, a culture taken, and the cavity irrigated with physiologic saline solution. The cavity was found to extend to the peritoneal reflection, having dissected superiorly the length of the vagina, to the anal margin inferiorly, to beyond the ischial tuberosity left laterally, and beyond the site of the episiotomy medially. Drains were inserted through a stab wound medial to the left ischial tuberosity and through the wide open episiotomy wound. The cavity was packed through the vaginal incision, and a "T" binder was applied. Packs were changed and drains shortened in 24 hours. All drains and the vaginal sponge were removed on the 6th day. Potassium permanganate douches and sitz baths were then instituted until discharge on the 11th day.

Postoperative examinations revealed excellent general healing and the presence of a painful scar at the site of the episiotomy along with a relaxed vaginal outlet. Excision of the painful cicatrix and perineorrhaphy were accomplished 4 months after the original operation. The patient left the hospital in 8 days. Follow-up examination showed a well healed, firmly supported perineum. The vagina admitted 2 fingers without discomfort. No pelvic abnormality was noted.

SUMMARY

A review of the literature from 1554 to 1948 reveals 188 cases of paravaginal hematoma.

Obstetric hematomas may be immediate or late and are anatomically classed as vulvar, paravaginal, intraligamentary or retroperitoneal, or a combination of these locations.

Early diagnosis and immediate active treatment are advisable because of the high mortality in severe cases.

A case of late post-partum vulvovaginal hematoma, exemplifying many of the points considered, is presented, and its treatment described

MEDICAL PROGRESS

TUBERCULOSIS

JOSEPH D WASSERSUG, M D *

QUINCY, MASSACHUSETTS

IT IS well nigh impossible for a single reviewer to encompass the entire field of tuberculosis, so vast are its ramifications. In a review such as this, one is forced to limit himself to the highlights of the year, and, even then, some significant contributions may be overlooked or touched upon only lightly.

The fact that tuberculosis mortality continues to show a gratifying decline cannot be overlooked. The death rate for tuberculosis, with few interruptions, has shown a continuous decline since 1910. In 1946, it was only 36.4 per 100,000 population,¹ which amounted to a 9.2 per cent decrease from the rate of 40.1 in 1945. In 1947 the death rate had dropped to 33 per 100,000,² and, according to the Metropolitan Life Insurance Company,³ a record low mortality may have been set in 1948. For their policyholders, the tuberculosis death rate declined from 32.3 per 100,000 in the first half of 1947 to 28.4 in the first six months of 1948, representing a reduction of 12 per cent. On the debit side of the ledger is the fact that in 1947 nearly 50,000 persons in this country still died of tuberculosis, nearly half of them between the ages of fifteen and forty-four. Although the over-all statistics are heartening, the time for complacency is still far off.

STREPTOMYCIN

So much additional evidence has accumulated during the past year for supporting the belief that streptomycin has a favorable influence on the course of tuberculosis as to dispel any doubt about its value. By far the largest series of cases treated with streptomycin is that reviewed by the Veterans Administration and the Army and Navy⁴ and their "current status" report is well worth reading. In summary, it may be said that some degree of benefit may be expected regardless of the site of infection.

or organs involved. In pulmonary tuberculosis, "streptomycin, in conjunction with bed rest, has been demonstrated to reverse the trend of progressive predominantly exudative moderately and far advanced disease in a formidable majority of cases." In cutaneous sinuses and fistulas, streptomycin has demonstrated a "striking usefulness." Although the end results in tuberculous meningitis and miliary tuberculosis are not quite so good as had been anticipated on the basis of the patients' initial responses, treatment with streptomycin is "mandatory" in these cases. Bone and joint lesions and urogenital lesions show a slow response to streptomycin, and the combination of surgery and antibiotic therapy is indicated in these cases. The results of treatment of lesions of the alimentary tract are "uniformly and remarkably favorable." For all forms of tuberculous peritonitis, streptomycin is regarded as an effective remedy. Since the drug brings about improvement in 80 to 90 per cent of cases of tracheobronchial and laryngeal tuberculosis, it should be considered as a prime form of therapy in such patients.

Aside from these generalities, probably the most notable advance clinically is the demonstration that the relatively high doses of streptomycin previously employed can be reduced to lower, less toxic, levels without any appreciable impairment in effectiveness. Along with this, there has been a gradual reduction in the cost of the drug so that it is now more readily available to noninstitutionalized as well as institutionalized patients. An amount of 1 gm daily in two divided doses at twelve-hour intervals for a period of one hundred and twenty days appears to be adequate, and 0.5 gm daily for as short a period as forty-two days may prove to be effective in some cases. If the latter scheme proves successful, toxic reactions from streptomycin may be reduced to the vanishing point.

When the therapeutic possibilities of streptomycin were first being explored it was wisely decided that additional measures other than bed rest had best be withheld so that any decision about the effectiveness of the drug would not be beclouded by other factors. Since streptomycin has already proved its effectiveness, this phase of evaluation can be said to be completed, and the time has now come when strict scientific evaluation is of less concern than the necessity of providing the patient with every form of treatment that will rid him of bacilli and restore him to health as quickly as possible. One may thus see streptomycin being given simultaneously with usual collapse treatments and, although such varied forms of therapy may be difficult to evaluate from the scientific standpoint, there is reasonable likelihood that the period of the patient's disability will be reduced. Streptomycin therapy is rarely definitive in the sense that it often does not produce complete clearing of the tuberculous lesions and that a considerable percentage of relapses occur. "Its most frequent usefulness appears, therefore," comments the committee,⁴ "to lie in conjunction with collapse therapy." The judicious use of streptomycin often makes collapse therapy a possibility in cases in which collapse would heretofore have been impossible or unlikely for one reason or another. According to the committee, the optimum time to induce collapse is during the first weeks of streptomycin therapy before resistance develops in the bacilli. From a practical standpoint, any patient with tuberculosis should receive any and all therapeutic measures, antibiotic and collapse, after a short period of observation has demonstrated their need.

Since the toxicity of streptomycin has been significantly reduced through the simple expedient of lowering of the average daily dose, only one significant drawback remains to its greater effectiveness. That drawback is the development of resistance (or, better, loss of sensitivity) of tubercle bacilli to the drug in some patients under treatment. Development of resistance is perhaps the chief reason for *not* using streptomycin in minimal lesions. In such cases the antibiotic is generally withheld since the prognosis is usually favorable without it, and, besides, should treatment with streptomycin become necessary at a later date, the drug would prove ineffective if loss of sensitivity had taken place. The increased resistance to streptomycin can be considerable and may be as high as a thousand times or higher. As a matter of fact, a curious paradox has recently been reported in the recovery from a patient of a strain of tubercle bacilli whose growth was considerably *enhanced* by the presence of streptomycin in the culture medium. The patient from whom this organism was isolated had been receiving the drug for ninety-six days for a pulmonary infection. In some cultures it was found that growth occurred in the presence of as

much as 100 microgm, whereas no growth was evident on the medium without streptomycin.⁵

The development of a loss of sensitivity of the tubercle bacillus during streptomycin therapy has recently been studied in a joint program of the Yale University School of Medicine and the Laurel Heights Sanatorium under the auspices of the American Trudeau Society.⁶ These studies are worth noting, for they are fairly typical of the universal experience in the development of resistance. A group of 16 patients with pulmonary tuberculosis were treated with 16 gm of streptomycin in six divided doses for a period of four months. Sputums or gastric washings were collected at routine intervals, and tubercle bacilli were isolated by culture from these specimens. After growth had been obtained, transfer of part of a suitable colony was made to a tube of modified Dubos-Davis medium for *in vitro* sensitivity tests. It was found that in all 16 cases, the strains of the bacilli isolated prior to treatment were highly sensitive to streptomycin. Loss of sensitivity (tenfold increase in resistance) began to appear by the end of the first month of therapy, together with conversion of positive sputum or gastric washings to negative in other cases as determined by culture. By the end of the third or fourth month of therapy, cultures were positive in only 9 of the 16 cases. Sensitivity tests of the organisms from these positive cultures indicated that all the organisms had developed a tenfold or greater increase in resistance. Five of these nine strains developed a tenfold to fiftyfold increase in resistance, in the remaining four strains the increase was a hundred to greater than two thousand times.

How streptomycin resistance can be a cause of therapeutic failure is graphically illustrated by a case of milary tuberculosis reported by Muschenheim, McDermott and Bunn.⁷ The patient was a twenty-one-year-old man whose milary tuberculosis was associated with cervical and mediastinal lymphadenitis of an extreme degree. Tubercle bacilli isolated from this patient were initially sensitive to less than 1 microgm of streptomycin per cubic centimeter of medium *in vitro*. With the institution of streptomycin therapy (30 gm daily), fever subsided, the superficial lymph nodes began to shrink visibly, stupor disappeared, the appetite became normal, and a rapid gain in weight ensued. For five weeks the patient seemed to be in complete remission. At that time, resistance of the organisms to streptomycin developed so that all the original symptoms returned with increased severity, and cultures of the tubercle bacilli revealed that the organism was now resistant to concentrations of streptomycin in excess of 1000 microgm per cubic centimeter. The temperature became elevated, the downhill course was progressive, and death ensued seven weeks after the clinical onset of the relapse and five months after the institution of treatment.

Considerations of this type temper one's enthusiasm for the drug and certainly provide good reasons for not using it in the early, minimal case of uncomplicated pulmonary tuberculosis whose prognosis is usually favorable on bed rest or collapse therapy. This experience further indicates that the action of streptomycin is still to be regarded as *suppressive* rather than curative.

Since streptomycin is far from an ideal therapeutic agent, some efforts are being made to use other therapeutic substances along with streptomycin for possible synergistic effect. One such agent being explored is para-aminosalicylic acid (PAS). Youmans and his co-workers⁸ have found evidence that such a synergism between streptomycin and PAS exists in mice, although it was possible to recover viable tubercle bacilli from all the mice treated regardless of the intensity of the therapeutic schedule. They note further "Since the usefulness of para-aminosalicylic acid for the treatment of clinical tuberculosis is not known, the importance of these results in relation to the treatment of clinical tuberculosis can only be a subject for speculation." McClosky, Smith and Frias,⁹ on the other hand, have carried out extensive researches on the toxicity, fate in the body and therapeutic efficacy of PAS in rabbits and guinea pigs. In these animals PAS had but little therapeutic effect by itself, and, when combined with streptomycin, it showed no more than a summation of effects without any indication of potentiation. In the light of these experiments, the value of PAS for human beings is doubtful.

Better results both experimentally and therapeutically have been obtained when streptomycin is combined with a sulfone such as promin or promizole. According to some investigators,¹⁰ promizole can be given for a period of years without any apparent major toxic effects. Promizole seems to have an inhibitory action on hematogenous tuberculosis although clinical evidence of its action is usually delayed until at least six weeks after the drug is first given. According to this concept, if streptomycin and promizole are given together, a prompt action is obtained from the streptomycin and a more delayed effect is obtained from the promizole. Considerations of this nature prompted Lincoln, Kirmse and DeVito¹⁰ to give this combination of drugs to 7 patients suffering from tuberculous meningitis. Promizole was administered orally in a total daily dosage of 0.5 to 1.0 gm, and this dose was gradually increased until a blood level of 2 to 3 mg per 100 cc was obtained. The streptomycin was given in doses of 0.5 to 2.0 gm intramuscularly, and, besides, all patients received 0.1 gm intrathecally daily at least during the first week of treatment. On this plan of management 6 of the patients survived and were apparently well three to eight months after institution of treatment. This is a remarkably good record for a disease as

terrible as tuberculous meningitis, although the authors are well aware of the fact that their patients have not been under observation for a sufficiently long period to be considered "cured."

Deserving of some mention is the report by Slotkin¹¹ in which streptomycin therapy is combined with injections of an ethyl ester of chaulmoogra oil. This author believes that the fatty capsule of the tubercle bacillus can be dissolved by the chaulmoogra esters, and thus the organism may be rendered more susceptible to the action of the antibiotic. A brief experimental and clinical experience on urogenital tuberculosis is cited in the preliminary report, but many more data are necessary before this form of therapy can be extended more widely into clinical practice. One direction that experimental investigation might take is suggested by the studies of Karlson and Feldman¹² on the subeffective dose of streptomycin in experimental tuberculosis in guinea pigs. These investigators wisely point out that in a study of the effect of two or more chemotherapeutic agents on an experimental infection, it is necessary that the dose of each drug be low enough so that one of the drugs alone will not be responsible for the total therapeutic response. As far as guinea pigs are concerned, their results indicate that if the daily dose of streptomycin is kept at 20 mg, it may be considered as being subeffective and suitable for testing the additive or synergistic action of other compounds.

PNEUMOPERITONEUM

During the past few years pneumoperitoneum has definitely emerged as a valuable form of collapse therapy on a par with pneumothorax if not actually surpassing it in many cases. Banyai,¹³ one of the pioneers to use this form of treatment as far back as 1931, has recorded his experiences and that of others in considerable detail. Mitchell and his colleagues,¹⁴ in North Carolina, have summarized the literature since 1937 in convenient tabular form and have described their own experience with this procedure, which covers 703 patients, 474 of whom were treated for three months or longer. Although they do not regard their results as offering "final proof of the efficacy and safety of pneumoperitoneum," they believe that pneumoperitoneum may be preferable to conventional collapse therapy or simple bed rest in cases with fairly extensive, predominantly productive disease with positive sputum provided the cavities are not too old or thick walled. If pneumoperitoneum is used in conjunction with phrenic paralysis, it is best to start pneumoperitoneum prior to surgery because with it one gains valuable information about the mobility of the diaphragm and its attainable elevation. In their own experience, Mitchell et al.¹⁴ found that the use of pneumoperitoneum for an average of fifty-four and a half weeks was responsible for 57 per cent satisfactory

results in 188 white patients and in 37 per cent of 286 Negroes, all of whom were "not amenable to conventional forms of collapse therapy"

Since pneumoperitoneum is a relatively new procedure exact definition of its indications and contraindications is lacking. According to Aronovitch, Caswell and Zadé,¹⁶ the indications for pneumoperitoneum may be summarized as follows: moderately advanced bilateral tuberculosis when artificial pneumothorax cannot be given, unilateral disease in which pneumothorax is impossible for one reason or another, to supplement phrenic crush, as an adjunct to artificial pneumothorax, as a preliminary measure in early bilateral cases, and for basal lesions with or without cavitation. Of 42 cases (1800 refills) carried out by this group, improvement was noted in 24, or 57 per cent, and there were no major complications.

Pneumoperitoneum has many advantages over conventional pneumothorax, some of which are listed by Anderson.¹⁶ Pneumoperitoneum does not interfere with the normal physiology of the intrapleural space in the way that pneumothorax does, and it does not create thickening of the pleura or produce an unexpandable lung. In bilateral disease, pneumoperitoneum has the advantage that both lungs can be collapsed by one injection of air. A further advantage is that the underlying lung can be visualized while treatment is continuing, and progress can be followed better than with pneumothorax. Pneumoperitoneum is a reversible procedure—one that can be induced, discontinued and reinduced almost at will. Spontaneous pneumothorax and bronchopleural fistulas are avoided. Anderson¹⁶ states:

Perhaps the outstanding advantage of artificial pneumoperitoneum over artificial pneumothorax, as far as the general practitioner is concerned, is the fact that fluoroscopic control is not essential. The operator simply injects enough air to inflate the abdomen snugly. He need not worry whether he is puncturing the lung, collapsing it too far, or losing the space—any of which complications may occur with artificial pneumothorax.

Fluoroscopic guidance is always valuable, however, even though it may not be essential in every case. Further experience will, of course, be necessary to determine whether pneumoperitoneum is preferable to pneumothorax in the outpatient or ambulatory management of tuberculous patients.

Complications with pneumoperitoneum are less frequent than with pneumothorax, but complications may occur. Air embolism is a possibility,¹⁷ and death from this complication has been noted.¹⁸ Sterile peritoneal effusions occur in about 8 per cent of the cases, and although they may require paracentesis, they do not necessarily indicate the abandonment of the pneumoperitoneum. On the other hand, peritonitis, either tuberculous or pyogenic, may be a serious complication and may necessitate discontinuation of pneumoperitoneum and the institution of suitable chemotherapy or

antibiotic therapy. Peritoneal adhesions may be seen in a great number of cases roentgenologically, but they seldom cause trouble. Penetration of abdominal viscera is a complication that is dreaded by beginners but is one that seldom occurs. Subcutaneous emphysema is a readily avoidable complication.

Although the technic of inducing and maintaining pneumoperitoneum varies somewhat from operator to operator, it is admittedly more simple than pneumothorax. Induction is usually carried out in the left lower quadrant under local procaine anesthesia, and the details can be found in any of the recent articles cited above. The amount of air given at the initial injection varies from 400 to 800 cc and refills, at intervals of seven to fourteen days, amount to anything from 500 to 1500 cc or more. Positive pressures are used, and the final pressure is kept under 20 mm of water, the average being 12 to 16 mm. There is no fixed rule in this respect, and individual variability must be taken into consideration. Manometric readings in pneumoperitoneum do not have the precise significance that they have in pneumothorax.

Although thousands of patients have been treated by pneumoperitoneum most of them have received treatment within the past few years, and suitably long follow-up material is not available. Trimble et al.¹⁹ have studied quite carefully 407 consecutive cases, of which 382 were adequately followed. In this latter group arrest of the disease was possible in 57 per cent, and an additional 13 per cent were definitely improved. It is to be noted that in their patients, arrest was achieved in 82 per cent of the minimal cases, in 79 per cent of those that were moderately advanced, and in 39 per cent of the far-advanced cases. Of 233 patients with cavitation, 47 per cent became arrested, and another 18 per cent were definitely improved. These results are at least as good as, if not better than, those in any comparable series treated by pneumothorax.

A recent editorial by Howlett²⁰ presents a sound appraisal of the present status of pneumoperitoneum without any bias or prejudice. He points out that there is still great divergence of opinion regarding the indications, effectiveness and usefulness of pneumoperitoneum in spite of the fact that it has been used for more than a decade. At present, he says, pneumoperitoneum seems to be heading for its phase of rapid expansion as a form of treatment, and, without doubt, some disillusionment with it will develop, especially when it comes to be used in forms of the disease in which it is not effective. Furthermore, as pneumoperitoneum ascends in vogue, it will be employed by more and more operators who are not adequately trained either in its administration or in the evaluation of the cases in which it may not be indicated. On the other hand, Howlett admits that he knows of no case "in which a physician has used pneumoperitoneum adequately

on enough patients for a sufficient period of time and has then discarded it as a procedure of no value." The chief danger of pneumoperitoneum, he believes, is not the procedure itself but the ease with which it may be given and the fact that the readiness with which it is tolerated by most patients may lead to its indiscriminate and excessive use. Howlett's editorial should be read by everyone attempting to perform pneumoperitoneum, especially the beginner.

Sporadic reports have appeared about the possible usefulness of pneumoperitoneum in the treatment of bronchial asthma. Attention is again called by Rubin and Gass²¹ to a case of intractable asthma that responded to this form of therapy. It is interesting to note that in the reproductions of the roentgenograms that accompany the article, considerable basal emphysema is present and that the amount of pneumoperitoneum used seems to be less than is customarily employed in the treatment of tuberculosis. Further investigation on the use of pneumoperitoneum in such cases is definitely indicated.

BCG

Evidence continues to accumulate that BCG (*Bacillus Calmette-Guérin*) is a safe and relatively efficacious vaccine for the control of tuberculosis. The policy of the American Trudeau Society²² regarding its use can be briefly summarized as follows: the degree of protection afforded by BCG is neither complete, nor is the duration of the induced immunity permanent or predictable. Nevertheless, it is recommended that the immunization be made available to medical and hospital personnel who are exposed to infectious tuberculosis, persons who are unavoidably exposed to infection in the home, inmates and employees of various institutions such as mental hospitals and prisons, and others who are considered to have a low resistance to tuberculosis and who live in communities in which the tuberculosis mortality is high. Vaccination of the general population is not recommended at present except under certain carefully controlled conditions. It is also not recommended that the vaccine be made available for general distribution since there is still some uncertainty about the most effective strain of BCG to be used and the most effective method of vaccination. It is the belief of the American Trudeau Society that the most effective methods of controlling tuberculosis are those already established, such as more intensive case-finding, segregation, intensive therapy and rehabilitation. BCG is not a substitute for approved hygienic procedures. A similar opinion regarding BCG is held by the United States Public Health Service^{23, 24}. It is perhaps unnecessary to add that BCG should only be given to persons who are negative reactors to tuberculin.

It is interesting to compare the limited experience with BCG in this country with that obtained elsewhere. In Scandinavia²⁵ vaccination with BCG has been established as a public-health measure since 1926, although it is by no means the only antituberculosis weapon employed. Other measures, such as tuberculin surveys and x-ray examinations, are intensively conducted, and, with such a vigorous program, the tuberculosis mortality in these countries has been reduced from 250 per 100,000 population in 1900 to less than 70 in 1944. So favorable were the early results with BCG that a national BCG laboratory was established in Norway in 1936, and, subsequently, BCG vaccination became obligatory for all tuberculin-negative student nurses. With the cruel German occupation of Norway in 1939, large numbers of tuberculin-negative young people were crowded into small and unhygienic quarters, and epidemics of tuberculosis were reported in all parts of the country. Political interference forced BCG vaccinations to be given surreptitiously, and yet, in spite of all these difficulties, the statistics at the end of this unhappy period indicated a "very considerable immunizing efficiency of the vaccine."

In Sweden, all medical students and pupil nurses are now tested before beginning hospital service, and the nonreactors are vaccinated²⁶. Conscripts in the services are vaccinated at the beginning of their term of service, and so are the majority of school children in the last class of primary school. In the city of Örebro the whole population has been tested, and the nonreactors have been vaccinated with BCG. All newborn babies are also vaccinated. On the basis of this experience, Malmros²⁶ urges BCG vaccination as a part of any modern tuberculosis program. He further advises that all vaccinated persons be checked at stated intervals and that those who have become tuberculin negative be revaccinated.

In this country, the most extensive experience with BCG is that reported by Aronson,^{27, 28} of the Office of Indian Affairs, and by Rosenthal and his colleagues²⁹ at the Municipal Tuberculosis Sanatorium in Chicago. Some of the statistics of the former investigator have been previously reviewed³⁰. The latter group has performed extensive laboratory investigations on BCG and conducted a study of the effects of vaccination on the following six groups of patients: newborn infants at the Cook County Hospital, medical students at the University of Illinois, infants born of tuberculous parents anywhere in Chicago, student nurses at the Cook County Hospital, children at a federal housing project, and inmates of a mental institution. Their studies, which have been in continuous operation for thirteen years, constitute the longest continuous experiment on BCG vaccination in the United States.

It can be said that these clinical experiments have proved reasonably successful. Of 2831 newborn

results in 188 white patients and in 37 per cent of 286 Negroes, all of whom were "not amenable to conventional forms of collapse therapy"

Since pneumoperitoneum is a relatively new procedure exact definition of its indications and contraindications is lacking. According to Aronovitch, Caswell and Zadé,¹⁵ the indications for pneumoperitoneum may be summarized as follows: moderately advanced bilateral tuberculosis when artificial pneumothorax cannot be given, unilateral disease in which pneumothorax is impossible for one reason or another, to supplement phrenic crush, as an adjunct to artificial pneumothorax, as a preliminary measure in early bilateral cases, and for basal lesions with or without cavitation. BCG

Evidence continues to accumulate that BCG (*Bacillus Calmette-Guérin*) is a safe and relatively efficacious vaccine for the control of tuberculosis. The policy of the American Trudeau Society²² regarding its use can be briefly summarized as follows: the degree of protection afforded by BCG is neither complete, nor is the duration of the induced immunity permanent or predictable. Nevertheless, it is recommended that the immunization be made available to medical and hospital personnel who are exposed to infectious tuberculosis, persons who are unavoidably exposed to infection in the home, inmates and employees of various institutions such as mental hospitals and prisons, and others who are considered to have a low resistance to tuberculosis and who live in communities in which the tuberculosis mortality is high. Vaccination of the general population is not recommended at present except under certain carefully controlled conditions. It is also not recommended that the vaccine be made available for general distribution since there is still some uncertainty about the most effective strain of BCG to be used and the most effective method of vaccination. It is the belief of the American Trudeau Society that the most effective methods of controlling tuberculosis are those already established, such as more intensive case-finding, segregation, intensive therapy and rehabilitation. BCG is not a substitute for approved hygienic procedures. A similar opinion regarding BCG is held by the United States Public Health Service.^{23, 24} It is perhaps unnecessary to add that BCG should only be given to persons who are negative reactors to tuberculin.

It is interesting to compare the limited experience with BCG in this country with that obtained elsewhere. In Scandinavia²⁵ vaccination with BCG has been established as a public-health measure since 1926, although it is by no means the only antituberculosis weapon employed. Other measures, such as tuberculin surveys and x-ray examinations, are intensively conducted, and, with such a vigorous program the tuberculosis mortality in these countries has been reduced from 250 per 100,000 population in 1900 to less than 70 in 1944. So favorable were the early results with BCG that a national BCG laboratory was established in Norway in 1936, and, subsequently, BCG vaccination became obligatory for all tuberculin-negative student nurses. With the cruel German occupation of Norway in 1939, large numbers of tuberculin-negative young people were crowded into small and unhygienic quarters, and epidemics of tuberculosis were reported in all parts of the country. Political interference forced BCG vaccinations to be given surreptitiously, and yet, in spite of all these difficulties, the statistics at the end of this unhappy period indicated a "very considerable immunizing efficiency of the vaccine."

In Sweden, all medical students and pupil nurses are now tested before beginning hospital service, and the nonreactors are vaccinated.²⁶ Conscripts in the services are vaccinated at the beginning of their term of service, and so are the majority of school children in the last class of primary school. In the city of Örebro the whole population has been tested, and the nonreactors have been vaccinated with BCG. All newborn babies are also vaccinated. On the basis of this experience, Malmros²⁶ urges BCG vaccination as a part of any modern tuberculosis program. He further advises that all vaccinated persons be checked at stated intervals and that those who have become tuberculin negative be revaccinated.

In this country, the most extensive experience with BCG is that reported by Aronson,²⁷⁻²⁹ of the Office of Indian Affairs, and by Rosenthal and his colleagues²⁹ at the Municipal Tuberculosis Sanatorium in Chicago. Some of the statistics of the former investigator have been previously reviewed.³⁰ The latter group has performed extensive laboratory investigations on BCG and conducted a study of the effects of vaccination on the following six groups of patients: newborn infants at the Cook County Hospital, medical students at the University of Illinois, infants born of tuberculous parents anywhere in Chicago, student nurses at the Cook County Hospital, children at a federal housing project, and inmates of a mental institution. Their studies, which have been in continuous operation for thirteen years, constitute the longest continuous experiment on BCG vaccination in the United States.

It can be said that these clinical experiments have proved reasonably successful. Of 2831 newborn

infants who were not in household contact with tuberculosis, there were 11 cases of tuberculosis in the vaccinated as against 39 in the controls. One death was recorded in the vaccinated, and 7 in the controls. In 1159 siblings the tuberculosis rate per thousand was five times as great in the controls as in the vaccinated. Among 256 newborn infants, when tuberculosis was present in the household and when isolation in foster homes was practiced in the controls and in the vaccinated alike, there were 2 cases of tuberculosis in the vaccinated as compared with 5 in the controls. In the federal housing project 699 children were vaccinated, 625 controls did not react to tuberculin, and 275 reacted to tuberculin and were not vaccinated. Considering the negative and positive reactors not vaccinated, there were 7 cases of tuberculosis, of which 2 were fatal, against no cases of tuberculosis in the vaccinated group. It was found that subsequent to vaccination a positive tuberculin test persisted as long as six years in the great majority of the children. Additional studies by Neiman and Loewinson³¹ have suggested that BCG inhibits the development of primary as well as secondary tuberculosis in infants. Their investigation, which is based on a study of 13,470 chest roentgenograms, furnishes additional proof of the efficacy of BCG.

Since successful vaccination with BCG converts a negative reactor to positivity, the vaccine should not be used in areas where tuberculosis mortality and morbidity are low and where tuberculin negativity is prevalent. The chief exponent of this viewpoint is Myers,³² who has repeatedly pointed to the admirable accomplishments in Minnesota, where tuberculosis has been largely eradicated. This has been achieved without the use of vaccination and through rigid adherence to sound public-health principles. To quote from Myers:

The tuberculin test is our only refined epidemiological agent. Indeed, it is only through its continued use that total eradication can be achieved. So-called immunizing substances, such as BCG and the vole tubercle bacillus, which sensitizes the tissues to tuberculo-protein, could serve no purpose except as a smoke screen for the tubercle bacillus in Minnesota. If used, they would nullify our most effective weapon—the tuberculin test. Moreover, their efficacy even in tuberculin control has never been proved in any sense of the word. They remain in the same position as their dozens of predecessors, namely, the theoretical and experimental stage. In parts of the world where BCG has been used, no achievement in tuberculosis control has been reported that even remotely approaches that in the United States, where sound epidemiological methods have been in vogue.

It is obvious, however, to the critical student of the subject that the situation in the United States, where "sound epidemiological methods" have been allowed to flourish unhampered by war, is entirely different from that in the devastated nations of Europe or some of the backward countries of South America. Even in the United States the situation in Minnesota may be likened to a safety zone that lies in the midst of streaming traffic. To carry the

analogy a bit farther, the wise Minnesotan will remain on his little island if he wishes to retain his health. To travel abroad without any immunity might prove particularly hazardous. Of course, if he so desired, he might remain where he is until traffic around him quieted down, but that might take a good many more years. In brief, Myers's argument applies very well at the present time to Minnesota. It does not, as yet, apply to the rest of humanity.

BACTERIOLOGIC CONSIDERATIONS

Although there has been a constant interest in the discovery of improved methods for culturing tubercle bacilli, there is no doubt that this interest was given considerable impetus by the reports of Dubos³³ and Dubos and Davis³⁴ on the use of liquid mediums for the rapid and submerged growth of these organisms. So reliable are the cultural methods at the present time that they have to a large extent replaced the more costly animal tests. Cultural methods have the additional advantage that they are superior in disclosing not only small numbers of virulent mammalian bacilli but also tubercle bacilli of low or moderate virulence. According to Corper and Bain,³⁵ the chief advantage of the animal test is that it overcomes the problem of eliminating the undesirable contaminating organisms without injury to the virulent tubercle bacilli. They have found, however, that by the use of trisodium phosphate in the culture medium, this disadvantage of the culture method is largely overcome.

The Dubos medium is being used widely for the culture of material obtained directly from the patient for the identification of tubercle bacilli. Goldie³⁶ reports that of 400 sputums examined by this method 34 were positive by culture and negative by smear. He states that compared with other culture methods, "the use of the Dubos medium is inexpensive, easily learned by an average technician, suitable for daily examinations of a large number of specimens, and, what is more, offers the advantage of a rapid (within 8 to 15 days) culture diagnosis of sputa containing relatively small numbers of *M. tuberculosis*." Folev³⁷ has studied 197 specimens obtained from various sources by both culture and inoculation methods. He believes that the method is valuable but points out that saprophytic mycobacteria from urine and gastric contents as yet cannot be sufficiently differentiated from tubercle bacilli for the exclusive use of these mediums for the specific diagnosis of tuberculosis. In these cases animal inoculation studies must be done for positive identification of the organism.

Cultural methods are of value not only in detecting tubercle bacilli but also in testing various antibiotic and chemotherapeutic agents. Although many such reports have appeared in the literature in the past year, only one is cited here as being illustrative of its value. Wong et al.³⁸ have noted

that the earlier attempts to demonstrate any antibiotic activity of subtilin *in vitro* by use of Long's synthetic medium have ended in inconclusive results. They therefore tested subtilin against a suitable strain of human virulent tubercle bacilli in Dubos medium and found that under the conditions of the test a 1:400,000 dilution of subtilin regularly inhibited the growth of these organisms and that dilutions of 1:20,000 were bactericidal. Rapid testing of new antituberculosis substances can thus be achieved through the use of the Dubos medium. The simple medium of human blood and glycerin, described by Dunphy and Fousek,³⁹ may also prove valuable in this direction.

Arguments have appeared from time to time supporting the use of alcohol as a disinfectant for both tubercle bacilli and other micro-organisms. The latest contribution to this argument is that presented by Smith,⁴⁰ and it is worth the attention both of private practitioners who have occasion to deal with tuberculosis and of hospital administrators. Smith cites extensive literature of this subject and his own many experiments. He finds alcohol to be an effective disinfectant against tubercle bacilli if attention is paid to the type of contamination and the concentration of the alcohol employed.

SURGICAL CONSIDERATIONS

In recent years the indications for pulmonary resection have come to be clarified and the procedure standardized in much the same way as thoracoplasty. According to Moore⁴¹ the indications for resection of tuberculous lungs include thoracoplasty failure, basal disease that fails to respond to conservative measures, endobronchial disease associated with tension cavities or pulmonary suppuration, tuberculoma and the so-called "destroyed lung" with extensive caseation and cavitation. Moore believes that the contralateral lung should be comparatively free from disease, or that any existing focus should be relatively stable or arrested. He further states that he can see "no sensible reason why the operation should be attempted in patients who have had bilateral disease and whose vital capacity is so low that pulmonary resection leaves them hopeless cripples, even though it may convert their sputum to negative."

At present, as Clagett and Seybold⁴² point out, the greatest hazard to patients with tuberculosis undergoing resection is late spread of the disease. This problem of late spread or reactivation has plagued every thoracic surgeon, and, in every case, statistical surveys of late results are found to be definitely inferior to the immediate mortality or morbidity. This is understandable for two reasons: tuberculosis is a generalized disease, and the removal of the most obvious focus does not rid the patient of his infection or alter his immunologic reaction to the tubercle bacillus, microscopic amounts of "spilling" during the operation into the un-

resected lung may not be immediately noticeable, and yet the organisms have been "planted" only to make their visible appearance at a later date.

The limited and restricted role that resection must play in the treatment of tuberculosis is brought out in the figures cited by Clagett and Seybold.⁴² Of 29 patients operated upon in their series (14 cases of lobectomy and 15 of pneumonectomy) 19 were clinically well and had sputum free of tubercle bacilli. Four patients were dead, 5 had active disease, and 1 was untraced. Sweet⁴³ also finds that the late results of resection are inferior to the immediate results and urges that at least one year be allowed to elapse before any report is made regarding such surgical procedures. He notes that of the 6 cases of lobectomy reported by Churchill and Klopstock in 1943, only 4 can be said to have done well three years later, and 3 of these 4 would probably have done equally well under thoracoplasty. "What appear to be very encouraging results at first," says Sweet, "have many times turned out to be disappointing when appraised some months later." He points out that of 13 reactivations following lobectomy (in a total of 27 cases), 11 occurred as a late complication. Of 10 reactivations after pneumonectomy (in a total of 36 cases), 7 were of late occurrence. It is important to note that Sweet's study includes only patients operated upon prior to the advent of streptomycin. It seems likely that streptomycin will minimize these complications, but it should also decrease the necessity for such radical surgery.

Perhaps the most enthusiastic proponents of lobectomy and pneumonectomy as a surgical treatment of tuberculosis have been Overholt and his group.⁴⁴ They believe that many of the patients for whom these procedures have been performed are "desperate-risk" patients whose death might otherwise have been anticipated with great certainty. "We feel," they say, "that *any salvage in this group of patients, regardless of how small, can be considered pure gain*." Their analysis of 88 patients treated by 92 resections and followed from two to twelve years shows that 68 patients could be considered as reasonable risks and 24 were desperate risks. Among 58 patients treated by pneumonectomy, there were 13 deaths in the sixty-day postoperative period and 11 late deaths, making a total case fatality of 41 per cent. Among 33 patients treated by lobectomy, there were 3 postoperative deaths and 3 late deaths. Only 14 of the 33 were clinically well and had consistently negative sputum. It must be noted that these statistics, too, antedate the use of streptomycin.

That streptomycin is a drug of much benefit in the management of surgical patients is already borne out by experience. What effect the drug will have on the incidence of late spreads, however, is still not known. Glover et al.⁴⁵ have cited their experience with streptomycin in conjunction with resection,

and their results, to date at least, are encouraging. They suggest that prophylaxis against immediate spread may be obtained and some other surgical complications may be reduced by streptomycin, and the doses needed to accomplish this may be smaller than those generally required for therapy. They believe that if the surgical mortality can be further reduced by a decrease of such complications, the indications for radical surgical treatment will be broadened. It seems to me, however, that although the *indications* may be broadened by the use of streptomycin, the over-all necessity for radical surgery may be reduced.

It may be well in this discussion of surgery to call attention to two procedures or technics that may prove of value in certain cases. The first is decortication of the lung in organizing hemothorax and empyema. In these cases the lung is bound down by a thick shell of fibrinous membrane that severely restricts respiratory activity. In certain cases it is possible to peel this membrane off, and one can then actually see the lung re-expand to fill completely the thoracic cavity. Lowe⁴⁶ reports 3 cases in which the decortication procedure was performed, in 1 of which the patient had tuberculous pleurisy and atelectasis. The postoperative course was excellent, and the patient gained weight and was relieved of his respiratory disability.

The second technic worth mentioning is the use of lucite spheres that are inserted into the thorax to assist in collapsing the lung in some cases of extrapleural pneumonolysis. Cases chosen for this procedure are those that would ordinarily be considered candidates for thoracoplasty, but the procedure has the advantage of less chest deformity. Although the indications for this operation are reasonably well established, it should be pointed out that there is only one year's experience and 30 operated cases behind this method and that it would be well to follow these patients for a longer period before the exact role of lucite plombage in the treatment of pulmonary tuberculosis can be evaluated. The authors⁴⁷ are themselves cognizant of this fact and make note of it in their paper.

REHABILITATION AND PSYCHIATRIC ASPECTS

It is safe to say that there has been more nonsense written about rehabilitation as it pertains to tuberculosis and about the mental attitude of tuberculous patients than there has been on any other phase of this complicated disease. Some of this stems from the fact that each specialist, be it social worker, rehabilitation expert or epidemiologist, is so concerned with his small specialty that he fails to see the forest because of his emphasis on an individual tree. Clinicians, too, have been accused of looking too closely at the patient's lungs to the exclusion of the body and soul in which the lungs are but a small part. Nevertheless, it does not follow, as some have suggested,⁴⁸ that the

clinician has to be "assisted by medical social workers, institutional and public health nurses, occupational therapists, and librarians" to realize the total portrait of the drives and dreams of the men and women who submit themselves to his care. Any good doctor does all that in his daily handling of his patients.

Pinner⁴⁹ points out that reports on the final results of rehabilitation are still too few to be significant. He states

That rehabilitation work is a necessary and important part of the successful treatment of many patients is quite generally accepted, it has come into its own during the last quarter of a century, in word and program, if not in action and reported results. If advocates of any medical or surgical treatment of tuberculosis had, for twenty or even ten years, written profusely on plans, methods, set-ups, theory and — the philosophy (a beloved misnomer!) — of some treatment without publishing statistically acceptable reports of results in terms of numerically significant case reports, they would, by now, find their treatment pretty well discredited. But this is, in essence, the present status of rehabilitation work.

For those who are interested in detailed discussions on the psychiatric appraisal of the tuberculous person, two recent articles^{50, 51} may prove helpful. The impression that one gains from these articles, however, is that the tuberculous patient is an exceedingly complicated person, buffeted by the storms of his emotions and anxieties. The implication is that many tuberculous patients should have the benefit of a psychiatrist in their routine management. As a matter of fact, another author⁵² states

There is a real challenge to psychiatry in the coming years to contribute materially to the improvement of the tuberculous. To do this, there must be close co-ordination of effort between individuals and agencies dealing with tuberculosis and mental hygiene. With the appearance of national interest in the mental hygiene movement, and its sponsoring through federal and state appropriations, the means are now available for the formation of a unified program of medical, psychiatric and sociologic treatment of the patient with tuberculosis.

Yet, it seems to me, the problem is far less involved. After all, as Dufault⁵³ points out, the personality of the tuberculous patient is, on the whole, uncomplicated.

He has his whims, his quirks, his idiosyncrasies, no doubt, but they run along the lines of yours and mine. He knows anger and resentment — and who does not? — but he is familiar with appreciation and gratitude. He can laugh or cry, snile or frown, talk or sulk, according to his moods. These are normal behavior traits which sound their harmonious or discordant notes in the shop and in the office as well as in the sanatorium.

It is well to note that this evaluation comes from one who has spent many years in the study of tuberculous patients and is not based on an "interview" that lasts an hour or two.

Perhaps the best of the recent discussions that deal with the psychology of the tuberculous patient is that by Moorman.⁵⁴ His experience in the treatment of the tuberculous has also extended over a great many years. Moorman believes that on a

broad psychosomatic basis every patient with tuberculosis is sick in mind as well as in body. That does not mean, however, that every victim of the disease needs the attention of a psychiatrist. "With rare exceptions," says Moorman, "the tuberculous patient needs only a wise phthisiotherapist who knows that mind and body are so interdependent that there can be no life when they cease to function as one." He adds that under ordinary circumstances the patient's interest should not be divided between several doctors, and his confidence in his attending physician should not be disturbed. On the average, the suggestion that a psychiatrist should be called to assist in the management of the case would only serve to spotlight the patient's mental aberrations "and aggravate his psychic conflict which otherwise might have resolved in the course of time almost, if not quite, unconsciously."

Since there is often a relation between the patient's mental state and the problem of irregular discharge from the sanatorium, the exhaustive study of such discharges by Tollen⁵⁵ is worth particular mention. Although his analysis of the situation is based on the experience of the Veterans Administration, the conclusions that he reaches have much wider applicability. It is apparent that a great deal of the responsibility of irregular discharges lies with the first physician who "breaks the news" to the patient that he has tuberculosis. The understanding and the reassurance that the patient receives from his doctor are far more important in creating a frame of mind conducive to successful hospitalization than any help the patient receives from others. In other cases, inadequate personal attention by the physician at the sanatorium is cited as a cause of premature departure of the patient from the hospital. Among the many suggestions that are made for correcting some of the evils that now exist, an excellent one is redefinition of the term "against medical advice." It is pointed out that if the staff doctor *knows* that a particular veteran requesting discharge will receive proper care at home and if no local health ordinance is violated, it should be unnecessary to discharge a patient "against advice" even though he still requires positive treatment for tuberculosis. Many other valuable suggestions are advanced by Tollen, and his article should be read by all sanatorium directors and their professional subordinates.

CASE 35121

PRESENTATION OF CASE

First admission A thirty-two-year-old woman entered the hospital for treatment of an old knee injury sustained two and a half years previously, when she severely bumped and twisted the left knee in a fall from a stepladder.

The initial pain and swelling subsided within a few weeks, and she was able to walk about fairly well despite some aching pain, stiffness and slight weakness, which persisted for about one year. Nine months before entry she again severely wrenched the left knee while running and subsequently suffered pain and stiffness on walking. Occasionally the knee gave way under her, although it never really locked. She consulted a doctor, who noted bulging and tenderness of the medial side of the left knee joint. X-ray films were reported as normal. An operation was performed, with removal of a torn medial meniscus. Following operation the knee continued to be painful, and she was unable to extend it completely, despite physiotherapy. Approximately five months later the knee was re-explored, and a loose body removed. This failed to bring any improvement, and the stiffness, failure of extension and aching pain continued.

The past history was noncontributory except for congenital syphilis manifested by interstitial keratitis of the right eye, which was intensively treated by arsenicals, bismuth and penicillin. The blood Wassermann reaction continued to be positive despite therapy.

Physical examination showed a well developed and well nourished woman. There was interstitial keratitis of the right eye, but the pupils reacted to light and accommodation. The left knee was held in 20° permanent flexion, with a flexion swing of 60°. There was considerable tenderness on palpation of the joint, most marked laterally.

The temperature was 98°F, the pulse 70, and the respirations 20. The blood pressure was 135 systolic, 80 diastolic.

Examination of the blood disclosed a white-cell count of 8100, with 81 per cent neutrophils. Both the blood Wassermann and Hinton tests were positive. X-ray films of the left knee showed that the joint surface was smooth, but the space was narrowed, and there was marked thickening of the soft tissues of the joint space. There was no bone destruction (Fig 1 and 2). The right knee showed no definite abnormality. A tuberculin test in a dilution of 1:100,000 was negative.

The knee was manipulated under anesthesia and brought to as much extension as possible, but there remained 20 to 25° fixed flexion. Following this the temperature spiked daily to 100 and 101°F for about five days. She then became afebrile and on exercise function improved considerably so that she was able to flex the knee 80° and lacked only 5° of full extension.

Second admission (two months later) Following discharge the patient was able to walk with crutches and to continue her exercises. She still had diffuse soreness on walking and at times suffered from a burning pain over the medial aspect of the joint, even at rest. Use of the knee definitely aggravated the pain and swelling of the knee.

Physical examination was unchanged except for considerable increase in the swelling and thickness of the periarticular tissues of the left knee posteriorly as well as to each side. There was diffuse tenderness and increased warmth.

Laboratory studies showed normal urine and blood counts. The sedimentation rate was 36 mm in one hour.

On the second hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR WILLIAM S. CLARK This record represents a common problem in the differential diagnosis of

monoarticular joint disease. The basic phenomenon responsible for the symptoms and signs described here may range all the way from reversible, poorly understood inflammatory processes of the synovial tissues to highly malignant and rapidly fatal tumors. Adequate clinical information and sound clinical hypothesis are particularly important because it is sometimes difficult to obtain adequate tissue for examination from various joints for anatomic reasons. We assume that in taking this history particular attention was paid to the possibility of involvement of other joints. Usually, in taking a history, we ask the patient indirect questions, inquiring about arch supports, lumbago or sciatica, and in this manner we frequently find that the presumed monoarticular disease is a

process. We can therefore focus most of our attention on the findings in the knee. The original symptoms followed an injury. This is a common story in joint involvement, regardless of the underlying process. A meniscus was removed at a previous operation, but there is no information concerning the pathology at that time. I am particularly interested in knowing if the synovial fluid was hemor-

FIGURE 1

part of a generalized type of joint involvement. However, on the basis of the information we have been given we will start with the assumption that this process was localized in one joint. It is also noted that there were no constitutional manifestations such as fatigue, weight loss or fever to indicate that this monoarticular joint involvement was related to a systemic disease such as rheumatoid arthritis or a chronic infectious

FIGURE 2

rhagic or not at that time. That operation apparently did not result in much improvement.

As far as the laboratory work is concerned, two facts may be significant. The sedimentation rate was elevated, and the blood Hinton test was positive. A negative tuberculin test in a dilution of 1:100,000 is not significant because joint tuberculosis can be present with a negative test using even higher concentrations.

May we see the x-ray films?

DR. STANLEY M. WYMAN: We have a single set of films taken of both knees, and they show the prominence of soft-tissue shadows adjacent to the left knee, particularly on the medial aspect and, to a lesser extent, laterally. This is well seen extending posteriorly to the joint. I believe the nature of the soft tissue is more consistent with a

mass than with fluid in the joint space or simply thickening associated with infection. The cortical surfaces of the left knee appear preserved, but there is extensive osteoporosis in the femur and in the tibia particularly on the femoral side in the region of the condyles. There are tiny areas of increased density within the soft-tissue mass, which suggests flecks of calcification.

DR CLARK: There are a number of lesions that might be considered. In spite of the absence of constitutional manifestations, we must consider the possibility of monoarticular rheumatoid arthritis. It is difficult to make such a diagnosis during a small segment of the course of the illness. Usually, such a conclusion is based on following the patient for a period and by eventually ruling out other possibilities. The anteroposterior x-ray film reveals changes in the bones consistent with that diagnosis. However, the periarticular thickening is more than one would expect in rheumatoid arthritis, in spite of the fact that synovial tissue proliferation is a basic part of its pathology. Furthermore, the subchondral destruction in the lateral view is more complete and more localized than we usually see in rheumatoid arthritis. Tuberculosis of the knee must be considered in this differential diagnosis. The x-ray films do not suggest an infectious process, and tuberculosis is not indicated by systemic manifestations. The marked soft-tissue swelling is against that diagnosis. Syphilis must be mentioned. Almost every form of joint disease has been attributed to this infection. I suspect that much of the syphilitic arthritis reported in the literature is actually related to rheumatoid arthritis. Gummas of the joint do occur, and they are in almost all cases related to bone. In my experience, the 2 proved cases of syphilitic involvement of the knee have been gummas of the patella. The problem of Clutton's joints (arthritis associated with congenital syphilis) need not be considered in spite of the presence of apparently healed interstitial keratitis. The fourth diagnosis we have to consider is tumor. I give greater weight to this possibility after seeing the great amount of thickening in the x-ray films. There are two types one might encounter in joints. The first is the benign giant-cell tumor of synovia, usually referred to now as pigmented villonodular synovitis. For those not familiar with this terminology, in relation to benign synovial tumors, I would like to give a word of explanation. Pigmented villonodular synovitis is a term applied by Jaffe¹ to the yellowish-brown, tumor-like lesion of the synovial membrane reported in the literature since 1865. This lesion has also been called benign giant-cell tumor of the synovial membrane, xanthoma, xanthogranuloma, xanthomatous giant-cell tumor and myeloplaxoma. Its morphology is well known to pathologists. We have recently analyzed 10 such cases here. The patients were of both sexes. The

ages ranged between seventeen and eighty years. The duration of symptoms had been from a few hours to fifteen years. There was monoarticular involvement in all cases, with a knee involved in 70 per cent. The patients usually complained of recurrent joint pain. X-ray changes were present in 30 per cent. The characteristic finding was bloody synovial fluid with counts ranging from 28,000 to 2,000,000 red blood cells per cubic millimeter.

The second type of tumor is the synovioma or synovial-cell sarcoma. This is not a common tumor, and I have had very little experience with it. I have drawn chiefly on the literature for information.² The synovioma can produce this picture with these symptoms. I am not so certain about the x-ray findings of bone destruction. The synovioma is not ordinarily confined to the joint cavity, and may extend beyond the joint into adjacent structures.

I had the original impression that this knee involvement was either monoarticular rheumatoid arthritis or pigmented villonodular synovitis. Since seeing the x-ray films I favor tumor and would place benign giant-cell tumor of the synovia or pigmented villonodular synovitis as the more likely diagnosis.

DR WYMAN: I think the description as given by Dr Clark is most compatible with the x-ray findings—namely, a tumor. It has been my experience and that of others that this suggestion of fine calcification is not uncommon with synovioma. As to whether there is true bone destruction at all, it seems to me more like osteoporosis—atrophy of disuse. Therefore, I should consider synovioma primarily.

DR CLARK: I probably did not pay enough attention to the presence of flecks of calcium. I do not know whether there is actual osteoporosis in pigmented villonodular synovitis. I think Dr Castleman has seen one case with some involvement of the marrow by the tumor.

DR BENJAMIN CASTLEMAN: Yes.

DR CLARK: We have been inclined to assume that the decalcification in pigmented villonodular synovitis is analogous to the decalcification that occurs in hemophilic arthritis. I would like to explain its symptoms by repeated joint apoplexies. Whether the atrophy comes from disuse or an autonomic phenomenon, we do not know. I agree that this does not appear to be the decalcification of something eroding into the bone or eroding within the bone.

DR MARIAN ROPES: Essentially I used the same type of reasoning as Dr Clark. I first thought of tuberculosis and rheumatoid arthritis. I tended at that time to rule out tumors on the fact that the patient had had two operations. Later, when we found that biopsy had not been done at either operation, a thing that occurs too commonly in opening a joint, I considered villonodular synovitis the most

likely diagnosis. Again, I ruled out malignant tumor, partly on the duration of the course.

CLINICAL DIAGNOSES

Traumatic synovitis
Villonodular synovitis?

DR CLARK'S DIAGNOSIS

Pigmented villonodular synovitis (benign giant-cell tumor of synovia)

ANATOMICAL DIAGNOSES

Synovioma of left knee, with metastases to vertebrae, clavicle, ribs, pelvic bones, peritoneum, abdominal lymph nodes, lungs and liver

Compression myelitis, twelfth dorsal vertebra
Decubitus ulcer, sacral region
Cystitis, acute and chronic, severe
Bronchopneumonia
Interstitial keratitis

PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY This knee was explored by Dr Edwin F Cave, who found a marked thickening with papillary excrescence of the synovial membrane. Some of the nodular excrescences showed a brownish, chocolate-colored staining, rather suggestive of villonodular synovitis. Microscopical sections, however, did not look like that, and we were inclined to think that we were dealing with malignant neoplasm, although it did not look like any synovioma that we had seen, and we were unable to name it. We sent the slides to Dr Jaffe, who said he did not know what it was and thought that it was probably a granulomatous lesion, although he could not rule out malignant tumor. We also sent them to Dr Granville Bennett, who said that he thought it was tumor but did not know what kind of tumor.

The patient at that time refused amputation and was permitted to go home after partial excision and fusion of the knee joint. Pain continued and became so severe that she returned a couple of months later and consented to amputation. At that time very extensive neoplastic involvement of the remnant of the knee joint was found. Once again she was allowed to go home, and a few months later developed evidence of metastases in the lower spine, with transverse myelitis. She finally died of complications of the myelitis. At autopsy we found metastatic lesions in the bones, including the ribs and several vertebrae. There was one minute nodule in the lung, one in the liver and many serosal implants throughout the peritoneal cavity, one of which had invaded the ovary, and

a great many retroperitoneal nodes were involved. The distribution of the metastases was a most unusual one for any form of tumor. The metastases are no easier to classify than the primary tumor. Synoviomas, as I have seen them, surprisingly rarely show very much fibrous tissue, and yet this tumor was, in places, quite scirrhous. Characteristically, they show two types of cells, one of which appears epithelial, the other is spindle-shaped and suggests primitive mesenchyme. There are often clefts in the tumor that appear to be lined with the epithelial elements. I could find no such areas in this case. A rather noticeable feature about this tumor was that many of the cells were coarsely vacuolated. We thought briefly of liposarcoma, but fat stains were negative. Some glycogen was demonstrated in the vacuoles. Neither the character of the cells nor the general architecture of the tumor corresponds to what is ordinarily seen in synovioma. Yet the primary location of the tumor in the synovia of a knee joint is characteristic. I think synovioma is the diagnosis we have to make, despite the rather atypical histologic appearance. Our experience with synoviomas is that they have all been very highly malignant, and early metastases have been the rule.

There was one very interesting phenomenon, which I have never noted before. On the edge of the metastases in the liver and lung the neighboring parenchymal epithelial cells had been stimulated to marked growth. In the lung, for instance, the neighboring alveoli showed a lining of high columnar epithelial-like pulmonary epitheliomatosis. In the liver there was marked proliferation of bile-duct epithelium all around the metastasis as if some growth-stimulating substance were being excreted by the tumor. The fact that this phenomenon was seen in two different organs, each time in close approximation to a metastatic nodule, makes me believe that it was not coincidence. I think there must have been some such peculiar growth stimulation associated with this tumor.

A PHYSICIAN If a biopsy had been taken at the first operation, it would have helped the treatment, would it not?

DR MALLORY If the diagnosis could have been made on the original operation, which I think is doubtful in view of the fact that several months later three pathologists disagreed on the diagnosis, immediate amputation might have made a difference. Some six months was lost in this case.

DR CLARK Most people ignore their lame knees until a diagnosis is of very little help if it turns out to be a malignant tumor.

The characteristic finding was bloody synovial fluid with counts ranging from 28,000 to 2,000,000 red blood cells per cubic millimeter.

The second type of tumor is the synovioma or synovial-cell sarcoma. This is not a common tumor, and I have had very little experience with it. I have drawn chiefly on the literature for information.² The synovioma can produce this picture with these symptoms. I am not so certain about the x-ray findings of bone destruction. The synovioma is not ordinarily confined to the joint cavity, and may extend beyond the joint into adjacent structures.

I had the original impression that this knee involvement was either monoarticular rheumatoid arthritis or pigmented villonodular synovitis. Since seeing the x-ray films I favor tumor and would place benign giant-cell tumor of the synovia or pigmented villonodular synovitis as the more likely diagnosis.

DR WYMAN: I think the description as given by Dr Clark is most compatible with the x-ray findings—namely, a tumor. It has been my experience and that of others that this suggestion of fine calcification is not uncommon with synovioma. As to whether there is true bone destruction at all, it seems to me more like osteoporosis—atrophy of disuse. Therefore, I should consider synovioma primarily.

DR CLARK: I probably did not pay enough attention to the presence of flecks of calcium. I do not know whether there is actual osteoporosis in pigmented villonodular synovitis. I think Dr Castleman has seen one case with some involvement of the marrow by the tumor.

DR BENJAMIN CASTLEMAN: Yes.

DR CLARK: We have been inclined to assume that the decalcification in pigmented villonodular synovitis is analogous to the decalcification that occurs in hemophilic arthritis. I would like to explain its symptoms by repeated joint apoplexies. Whether the atrophy comes from disuse or an autonomic phenomenon, we do not know. I agree that this does not appear to be the decalcification of something eroding into the bone or eroding within the bone.

DR MARIAN ROPES: Essentially I used the same type of reasoning as Dr Clark. I first thought of tuberculosis and rheumatoid arthritis. I tended at that time to rule out tumors on the fact that the patient had had two operations. Later, when we found that biopsy had not been done at either operation, a thing that occurs too commonly in opening a joint, I considered villonodular synovitis the most

in such a case as this may be regarded as practically pathognomonic. And the third is the fact that an apparently satisfactory barium enema was repeated on the following day. This suggests that the Surgical Service was anxious to learn whether spontaneous reduction had occurred or possibly that they hoped to be able to reduce the intussusception by hydrostatic pressure. From the appearance of the films I judge that reduction did not occur.

We must now consider the causes of intussusception in adults. The acute, spontaneous condition observed in children is very rarely, if ever, seen in adults. Furthermore, the recurrent nature of this man's complaint, as well as the presence of diarrhea with blood persisting between the acute episodes, makes me believe that there was some underlying, intrinsic lesion in the bowel that precipitated the intussusception.

Apparently the commonest cause of this condition is submucous lipoma of the colon.* Bloody diarrhea can occur in this condition if there is ulceration of the mucosa overlying the tumor. Benign polyps of the colon have been described as the precipitating factor in intussusception in adults. Carcinoid of the ileocecal region has also, I believe, been described in this relation. I see no reason why any benign tumor of the colon, or possibly of the terminal ileum, might not have been at the root of this man's trouble. The same statement may be made of Meckel's diverticulum. However, I do not see how we can arrive at a positive conclusion concerning just what the lesion was.

On a statistical basis I shall say that submucous lipoma of the cecum or ascending colon is the most likely diagnosis, with mucosal ulceration and intussusception.

DR F THOMAS GEPHART. This patient's history suggested regional ileitis. When the Surgical Service first saw the patient he had developed this large, midepigastic mass and had the barium-enema findings of intussusception. It seemed unusual to see such a large mass result solely from intussusception without more marked signs of acute

intestinal obstruction. This was one point in favor of the diagnosis of carcinoma of the transverse colon. We realized the patient might well have an intussusception, but since he had no signs of acute obstruction, we decided to prepare him for bowel surgery for two days with antibiotics, start a Miller-Abbott tube and transfuse him, watching carefully for signs of obstruction.

After induction with ether anesthesia the large, midepigastic mass had disappeared, and a small firm mass could be felt in the right lower quadrant. At operation the intussusception was found to be reduced, and a hard, doughnut-shaped tumor was found involving the cecum near the ileocecal valve. Though the tumor completely surrounded the bowel, the lumen was not obstructed.

CLINICAL DIAGNOSIS

Carcinoma of the colon, with intussusception?

DR GIDDINGS'S DIAGNOSIS

Submucous lipoma of cecum, with intussusception

ANATOMICAL DIAGNOSIS

Adenocarcinoma of cecum, with previous intussusception

PATHOLOGICAL DISCUSSION

DR BENJAMIN CASTLEMAN. In the cecum surrounding the appendiceal orifice was an elevated, indurated and ulcerated circular tumor about 5.5 cm in diameter. The appendiceal os protruded into the center of the tumor. The appendix itself was slightly thickened. Microscopically, the tumor was the usual adenocarcinoma, invading but not extending through the muscularis. The ileocecal valve was not involved, nor were any of the regional lymph nodes.

Usually when a carcinoma produces intussusception it is the polypoid type. I suppose in this case the slight involvement of the muscularis and perhaps the unusual location of the tumor contributed to the mobility of the bowel. The intussusception must have included the appendix.

CASE 35122

PRESENTATION OF CASE

A thirty-eight-year-old man was admitted to the hospital complaining of cramps, diarrhea and weight loss.

The patient was in good health until one month before admission, when crampy, right-lower-quadrant pain, accompanied by right-lower-quadrant distention, appeared. This was occasionally associated with vague, left-upper-quadrant epigastric distress. The episodes were intermittent and occurred at any time of the day or night and were sufficiently severe to prevent sleep. There was no relation to eating. Some relief was obtained from belching or bowel movements. Until the onset of the illness he had been chronically constipated. A month before admission the bowel movements became loose and watery, and he had five or six diarrheal stools daily, which contained a few flecks of bright-red blood without pus or mucus. These symptoms lasted for five days and then disappeared for two weeks, when they recurred and gradually became more severe. The appetite diminished. On the night before admission he vomited for the first time. During the past year his weight went from 135 to 118 pounds because he did not have enough to eat.

His father was living, aged seventy-five, and had been operated upon eight years previously for "cancer of the stomach." A brother had been operated on for "cancer of the rectum" several years previously.

Physical examination showed an undernourished, underdeveloped man. The abdomen was moderately distended, and the lower half was tympanitic, more on the right than the left. The peristaltic sounds were normal. There was considerable direct and rebound tenderness in the right lower quadrant, with voluntary spasm. No mass was felt. There was mild bilateral costovertebral-angle tenderness. The left testicle was undescended, and a partially reducible left direct inguinal hernia was present. On rectal examination hemorrhoids were found and there was marked tenderness in the right vault, but no mass was felt.

The pulse was 88, and the respirations 20. The blood pressure was 120 systolic, 80 diastolic.

Laboratory examination demonstrated a normal urine. The white-cell count was 8800, with 88 per cent neutrophils. The hemoglobin was 12 gm. The stools were liquid, brown and guaiac positive. The serum protein, prothrombin time and cholesterol were all within normal limits. X-ray study of the chest demonstrated no abnormality. In the abdomen a plain film suggested a mass in the right upper quadrant, partially outlined by gas within the colon. On barium enema the barium flowed to the midtransverse colon, where a complete obstruction was met. Barium flowed along the margins of a lu-

menal mass for a short distance. There was a large palpable mass in this area. A sigmoidoscopic examination showed no abnormalities, but "the bowel seemed a bit spastic."

On the second hospital day a mass was felt to the right and below the umbilicus. On the following day it had moved to the left half of the abdomen to the level of the umbilicus.

An operation was performed five days after admission.

DIFFERENTIAL DIAGNOSIS

DR. W. PHILIP GIDDINGS: The salient points of this history are that the patient was a man of thirty-eight years whose symptoms were of one month's duration. There appear to have been two different sets of symptoms, both referable to the lower gastrointestinal tract. The first consisted of intermittent diarrhea with five or six loose stools daily and with small amounts of bright blood in the stools. The second comprised episodes of right-lower-quadrant pain of significant severity, accompanied by right-lower-quadrant distention, partially relieved by eructation or defecation and apparently attended by vomiting the night before admission.

There was a suggestive family history of gastrointestinal cancer. Physical findings directed attention to the right lower quadrant and were compatible with ileus. Under observation there was a palpable mass in the right lower quadrant, which twenty-four hours later had moved to the left side. Proctoscopy was negative, and the presence of blood in the stools was confirmed. Blood chemical findings were normal. The polymorphonuclear leukocytosis suggested an inflammatory component to the disease, but we do not know whether or not there was fever.

The finding of hernia and cryptorchidism on the left raises the question whether or not either might have been related to the present illness. However, the reducibility of the hernia rules it out as a source of trouble, and the likelihood that a tumor in an undescended left testis would cause primarily right-sided bowel symptoms seems small. I believe these conditions were not related to the present illness.

The barium-enema films are revealing. There was a convex defect in the midtransverse colon, with the margins of an obstructing, fairly smooth, intraluminal mass clearly outlined. This appearance was the reverse of the concavity with "shelf" formation commonly seen in carcinoma of the colon. It is, however, characteristic of intussusception.

In addition to the x-ray appearance, there are three reasons for believing that this man suffered from intussusception. The first is the recurrent nature of the acute episodes, with intervals of relief, suggesting repeated bouts of a process that relieved itself.

The second is the observed migration of a mass from the right to the left side of the abdomen, which

the people. The second is that governmental agencies must acknowledge and discharge their statutory obligations and that, in the instances covered by the present study, the communities of Greater Boston should accept all the financial aid that federal and state laws make possible.

The fiscal troubles in which the social and health services of the area find themselves are due to a variety of causes, and a variety of remedies, some of them drastic, are necessary to correct them. The failure mentioned above of governmental agencies, "charged with the legal duty to render certain services to people who meet clearly stated conditions," is an important cause, and it is appropriate to note that Greater Boston has received a smaller percentage of help from federal sources than the other areas with which it was compared — 94 per cent against an average of 118 per cent. Voluntary agencies should not use voluntary funds to pay for such services.

As corollaries to this principle, it should be established that when the provision of certain services has become widely accepted as a proper duty of government, it is mistaken community policy to support such services indefinitely from limited voluntary contributions, and that tax-supported agencies obtaining service from voluntary agencies should fully reimburse those agencies for the services received.

Needless duplication and overlapping of services, as they now exist, should be done away with, agencies should combine in some instances and should transfer their functions to competitive agencies and go out of business in others. Some services now supported by voluntary community funds should become self-supporting.

The Survey finally recommends that at the highest level a strong central agency should be established for fund raising, planning and budgeting, to replace its excellent but less adequate parents, the Greater Boston Community Fund and the Greater Boston Community Council.

In an area where "some of the newest and some of the oldest methods, and certainly some of the most tenacious traditions, in American public welfare and public health" exist, among more than 800 agencies, reforms may be difficult to institute. The

very number of agencies involved, however, indicates the inefficiencies that must be remedied. The writing on the wall is in red ink and is preceded by a dollar sign.

DISREGARDED SEEDBED OF THE TUBERCLE BACILLUS

For adequate control or eradication of a disease like tuberculosis it is essential to know the sources of the infection and how it is spread from those sources. The steady decline in mortality figures is usually interpreted as indicating that the sources of infection are becoming fewer and that the disease is becoming of minor importance. Studies in certain limited population groups, however, have indicated that incidence and mortality are actually independent of each other and that the amount of clinically active tuberculosis is the result of these two. Only a small proportion of attempts to determine the "source case" for any new patient with tuberculosis are successful, and this must mean that the majority of new cases arise from clinically unimportant or clinically unrecognized sources.

Medlar and his co-workers* attempted to discover some of the unrecognized sources through a careful study and analysis of the autopsy material from Bellevue Hospital. The large and varied clinical and autopsy material seen at that hospital offered an excellent opportunity to determine on the one hand the incidence of deaths from tuberculosis and on the other the incidence of unhealed tuberculosis in persons who died from other diseases. They analyzed the post-mortem data of all patients over fifteen years of age for the ten-year period, 1935-1944, in relation to age, sex, race, the presence or absence of caseous foci or cavities in the lungs, generalized miliary tuberculosis and tuberculosis as a primary cause of death or as an incidental finding in persons who died of other diseases and the clinical diagnosis in relation to the recognition of the tuberculosis that was found at autopsy. They looked particularly for caseous foci in the lungs, as indicated by areas of necrotic tuberculous pneumonitis, which, when they soften and are extruded, serve as a source from which tubercle bacilli may be

GREATER BOSTON COMMUNITY SURVEY

IT HAS BEEN apparent for some time that the per-capita expenditure for charitable purposes in Greater Boston has been more generous than in a number of comparable areas. It has not been so apparent that the returns from each of the multiplicity of agencies involved has always been on a commensurate scale. A multiplicity of competitive appeals has developed, moreover, each of which makes its demands upon the public conscience and the public purse. When the dollars themselves, in addition to shrinking in value, began to shrink in numbers, it seemed obvious to certain persons interested in the Greater Boston Community Fund and the Greater Boston Community Council that something should be done about it.

Accordingly, Robert Cutler, well known for his interest in the public welfare, was invited early in 1947 to form a committee of citizens to investigate the problem. This committee of 180 persons met in March, two years ago to launch the enterprise. The result was the Greater Boston Community Survey of the more than 800 voluntary and tax-supported agencies in 55 of the independent communities that make up the non-political and vaguely defined area known as Greater Boston.

The basic object of the Survey has been "to make sure that the charitable dollar annually raised in Greater Boston does the greatest good for the greatest number in the most economical, effective way." It has been carried on and its results finally approved by an executive committee of 16 members, who, at the beginning of their labors, selected Robert P. Lane, of New York, as director of the Survey. The report of the Survey has been accepted by the Committee of Citizens.

The task has been difficult and many of its problems unprecedented. As the director stated in his foreword to the final summary report, recently issued:

In the cities and towns of Greater Boston are found some of the country's oldest voluntary agencies, a few of them with some of the country's largest capital reserves, agencies established and for decades supported by persons bearing names that are honored throughout the country. Here are agencies that march in the forefront of advancing professional practice. Here are agencies that were once distinguished pioneers in important fields, still forgetful of their early glory. Here are some of the newest and some of the oldest methods, and certainly some of the most tenacious traditions, in American public welfare and public health. Here in these independent, self-governing communities, are found a local pride, a resistance to outside control, a determination to manage one's own affairs, that are the very pith of the American spirit. Tax-supported and voluntary alike, the social and health agencies of Greater Boston present both an unparalleled opportunity and an unparalleled challenge to any group of lay citizens and professional workers who undertake a survey of this ancient, complex and justly proud community.

The director further stated two "preconceptions" that might be accepted as basic principles wherever the activities and the support of any social agency are scrutinized. The first is that all agencies, regardless of their auspices and the source of their funds, are engaged on a common task for the benefit of all.

the people. The second is that governmental agencies must acknowledge and discharge their statutory obligations and that in the instances covered by the present study, the communities of Greater Boston should accept all the financial aid that federal and state laws make possible.

The fiscal troubles in which the social and health services of the area find themselves are due to a variety of causes, and a variety of remedies, some of them drastic, are necessary to correct them. The failure mentioned above of governmental agencies, "charged with the legal duty to render certain services to people who meet clearly stated conditions," is an important cause, and it is appropriate to note that Greater Boston has received a smaller percentage of help from federal sources than the other areas with which it was compared—9.4 per cent against an average of 11.8 per cent. Voluntary agencies should not use voluntary funds to pay for such services.

As corollaries to this principle, it should be established that when the provision of certain services has become widely accepted as a proper duty of government, it is mistaken community policy to support such services indefinitely from limited voluntary contributions, and that tax-supported agencies obtaining service from voluntary agencies should fully reimburse those agencies for the services received.

Needless duplication and overlapping of services, as they now exist, should be done away with; agencies should combine in some instances and should transfer their functions to competitive agencies and go out of business in others. Some services now supported by voluntary community funds should become self-supporting.

The Survey finally recommends that at the highest level a strong central agency should be established for fund raising, planning and budgeting, to replace its excellent but less adequate parents, the Greater Boston Community Fund and the Greater Boston Community Council.

In an area where "some of the newest and some of the oldest methods, and certainly some of the most tenacious traditions, in American public welfare and public health" exist, among more than 800 agencies, reforms may be difficult to institute. The

very number of agencies involved, however, indicates the inefficiencies that must be remedied. The writing on the wall is in red ink and is preceded by a dollar sign.

DISREGARDED SEEDBED OF THE TUBERCLE BACILLUS

FOR adequate control or eradication of a disease like tuberculosis it is essential to know the sources of the infection and how it is spread from those sources. The steady decline in mortality figures is usually interpreted as indicating that the sources of infection are becoming fewer and that the disease is becoming of minor importance. Studies in certain limited population groups, however, have indicated that incidence and mortality are actually independent of each other and that the amount of clinically active tuberculosis is the result of these two. Only a small proportion of attempts to determine the "source case" for any new patient with tuberculosis are successful, and this must mean that the majority of new cases arise from clinically unimportant or clinically unrecognized sources.

Medlar and his co-workers* attempted to discover some of the unrecognized sources through a careful study and analysis of the autopsy material from Bellevue Hospital. The large and varied clinical and autopsy material seen at that hospital offered an excellent opportunity to determine on the one hand the incidence of deaths from tuberculosis and on the other the incidence of unhealed tuberculosis in persons who died from other diseases. They analyzed the post-mortem data of all patients over fifteen years of age for the ten-year period, 1935-1944, in relation to age, sex, race, the presence or absence of caseous foci or cavities in the lungs, generalized miliary tuberculosis and tuberculosis as a primary cause of death or as an incidental finding in persons who died of other diseases and the clinical diagnosis in relation to the recognition of the tuberculosis that was found at autopsy. They looked particularly for caseous foci in the lungs, as indicated by areas of necrotic tuberculous pneumonia which, when they soften and are extruded, serve as a source from which tubercle bacilli may be

*Medlar E. M., Spain D. M. and Holliday R. W. Disregarded seed-bed of tubercle bacillus. *Arch. Int. Med.* 81:501-517 1945.

scattered within the lung and to the outside world. Since the results of this analysis are most revealing, some of the highlights are summarized.

With respect to race they found that in most cases in which tuberculosis was recorded in the autopsy records of Negroes it was the primary cause of death, whereas 29 per cent of white patients died from diseases other than tuberculosis. This suggests that if progressive tuberculosis becomes established in Negroes, they seldom survive long enough to die of other causes, whereas white persons often do. For that reason caseous foci were often mentioned as incidental findings in white patients.

With respect to age, it was found that tuberculosis was the cause of death in all patients under thirty years in whom unhealed tuberculous lesions were recognized, but the disease was the cause of death in only half the patients over seventy years old. Tuberculosis was diagnosed clinically in 89 per cent of the cases in which it was the primary cause of death. This varied with the age, however, for it was diagnosed in about 97 per cent of those under thirty years of age and in only 60 per cent of those over seventy years. Even in cases of tuberculous cavities in the lungs the diagnosis was made in only 70 per cent of the patients over seventy years of age. There was a general decrease in the clinical diagnosis of tuberculosis with the increase of the age of the patient.

It was also evident from these data that unhealed tuberculosis received little clinical attention in persons who died from other diseases. The clinical diagnosis of tuberculosis was recorded in less than half such patients with tuberculous cavities in the lungs.

The Bellevue pathologists also compared their autopsy data with the mortality figures for the same period for persons over fifteen years of age throughout the City of New York. The hospital material contained a somewhat lower proportion of persons over seventy years old. Proved tuberculous deaths in all ages were twice as frequent in the autopsy series as in the City series. The ratio between the Bellevue figures and those from the City was 1:1 for patients under thirty years and 3:9:1 for those over seventy years. About three fourths of the autopsied cases from Bellevue Hospital in patients

under sixty years of age who died from tuberculosis were from the special service for the treatment of diseases of the chest, whereas in the group over seventy years of age, more than two thirds of the cases were from other services. It therefore seems that the higher proportion of deaths from tuberculosis at Bellevue was not due solely to the fact that there is a large active service for chest cases in that hospital.

Another interesting observation emerged from a comparison of incidence of unhealed tuberculosis among autopsies in two periods — namely, from 1920-1922 and from 1940-1942. Since the mortality figures from tuberculosis declined markedly in this interval, it was expected that the incidence of unhealed tuberculosis in the autopsy material would show a corresponding decline. The data, however, showed little change in incidence of unhealed tuberculosis, but instead there was a shift in the age distribution of these lesions, there being proportionally fewer cases under fifty years of age in the latter period. This tends, of course, to reflect the trend in the aging in the population.

A comparison of two samples of data from the same generation — that is, those who were fifteen to twenty-nine years old in 1920-1922 and those who were thirty to forty-nine years of age in 1940-1942 — revealed two points: as the generation aged, the ratio of deaths from other diseases to the deaths from tuberculosis increased, and, in patients with unhealed tuberculous lesions, there was a decrease in the ratio of deaths from tuberculosis to deaths from other causes. Thus, the greater incidence of unrecognized disease in old people must be considered not only the result of the holdover of patients who survived from the time when the mortality (and presumably the incidence in young people) was high but also due to new cases occurring in older age groups.

Confirmatory evidence for this conclusion is also quoted from experiences of the Metropolitan Life Insurance Company, where employees originally having negative x-ray examinations and tuberculin tests have been followed for a number of years. The average age when these persons began their employment was twenty years, and yet 63 per cent of them were found to have acquired the disease from one to

ten years later. Moreover, 10 per cent were employed for over fifteen years before acquiring tuberculosis. A history of contact with known cases was elicited in only about 10 per cent of these new cases. Medlar and his associates believe, on the basis of their autopsy experience, that these infections are new ones acquired in adult life rather than latent ones too minute to be detected earlier. This is a good illustration of increments of tuberculosis in an adult population that was as free from demonstrable tuberculosis as it is possible to determine from x-ray studies.

In discussing their observations, Medlar and his co-workers bring out the fact that today the majority of persons ill with tuberculosis are restored to a state of clinical well-being and many survive for years to die eventually from some other cause. Throughout their life many of these persons continue to shed tubercle bacilli and thus constitute one part of the seedbed of this disease.

Data are also quoted to show that tuberculosis is not too well controlled. About two thirds of the deaths from tuberculosis in a single year in New York City occurred outside any hospital, and another third took place within a month of admission to a hospital. A significant proportion of patients with active tuberculosis leave the hospitals against medical advice, and many patients are admitted to the hospital only for clinical relapse of the disease. Furthermore, about 1 in every 8 newly discovered cases first becomes known through death registrations, and about half the patients with tuberculosis are discharged from hospitals either improved or unimproved. All these facts also relate to that part of the seedbed which is known.

The fact that unhealed tuberculosis is seldom found in the autopsy records of adults under thirty years of age when death was due to other diseases suggests that, if unaltered in its course, progressive tuberculosis is a highly fatal disease in young adults. The finding of unhealed lesions in increasing numbers of persons dead from other diseases, in proportion to those dead from tuberculosis, indicates that a progressive infection acquired in later life tends to be less explosive. Tuberculosis is therefore less likely to be suspected in persons over fifty years of age. This constitutes the unknown part of the

seedbed, which the autopsy data indicate contains approximately 1000 persons with cavity formation per 100,000 of the population.

According to these workers control of tuberculosis—that is, the decrease in the continuity of the disease—requires intelligent supervision of the seedbed to prevent the return to the soil of the factors that favor the tubercle bacilli. This means a planned follow-up study of all persons with unhealed disease, including those with x-ray shadows, regardless of whether their disease is considered active or inactive. In addition, an intensified search must be made for a cure, in a pathological as well as in a clinical sense, of those who have a progressive disease. “The seedbed must be eradicated if tuberculosis is to be eradicated.”

AMORY PRIZE AWARDS

THE American Academy of Arts and Sciences is the custodian of a substantial sum of money, the interest of which is available each seven years for the award of the Francis Amory Prize to one or more persons who in the preceding septennium have made notable contributions to the “treatment and cure of diseases and derangement of the human sexual generative organs in general, and more especially for the cure, prevention, or relief of the retention of urine, cystitis, prostatitis, etc.” It was the expressed wish of the donor that the prize be awarded preferably for some “cunning contrivance or invention,” but if such an invention was not forthcoming, other means to the desired end might be recognized.

The awards for the preceding septennium were conferred at a meeting on December 8, 1948, by the president of the Academy, Howard Mumford Jones, and Professor E. B. Wilson, chairman of the Amory Prize Committee. A cash prize of \$3500 was presented to each of six distinguished investigators. Dr. Alexander B. Gutman, of New York City, Dr. Charles B. Huggins, of Chicago, Dr. Willem J. Kolff, of Kampen, Holland, Prof. Guy C. Marran, of Edinburgh, Dr. George N. Papanicolaou, of New York City, and Dr. Selman A. Waksman, of New Brunswick, New Jersey.

In commenting on the work of these scientists, Dr Huggins, who made the principal address of the occasion, emphasized the close similarity between scientists and artists both are devoted to the creation of orderliness and the search for truth among a host of confusing details. Like other forms of art, science can be dull or elegant, but good science is capable of evoking the highest intellectual pleasure in its creator and his auditors. "Good science finds itself equally at home in an institute of the Arts as of the Sciences."

"Medical research differs from the purer but not necessarily more elegant branches of science in the peculiarity that human beings with illness are its essential reason for being." And despite the necessity for quiet and leisurely reflection for creative thought the investigation should always be mindful of the sick patient in the background.

Urology was set forth as one of the youngest of the developed medical specialties—one of the finest accomplishments of this age, there is now no urologic illness that cannot in some way be improved by therapy. "Within the past ten years the treatment of venereal disease—a tremendous problem—has been solved." Nevertheless, the genitourinary system is extremely vulnerable to disease—mostly infections and tumors, which at one time or another afflict more than half of all human beings, hence, much more research remains to be done.

Among the 1948 recipients of the Amory prize, Dr Gutman is notable for the discovery of the usefulness of serum acid phosphatase determinations in the diagnosis and management of malignant prostatic neoplasms. Dr Huggins's splendid work on the influence of several hormones on prostatic secretion and on the diagnosis and treatment of cancer of the prostate is of world-wide renown. Dr Kolff, following up the work of Abel, Rowntree and Turner, of Johns Hopkins, has developed a practical "artificial kidney" for the treatment of acute uremia. Prof Marrian shared in the Amory Awards because of his searching investigations of steroid hormones that affect the functions of the generative tract, leading to important diagnostic and therapeutic measures. Dr Papanicolaou's work on exfoliative cytology is coming to be widely

applied not only to the diagnosis of cancer in the organs of the genitourinary tract but also to malignant growths in the hollow organs generally. Dr Waksman's discovery of streptomycin has been a major factor in the triumphs of current urologic therapy.

Dr Huggins concluded his Amory address with the following stirring words:

We are all impressed by the vigor and power of the human mind as demonstrated by the use of the scientific method. Science is not concerned with whether its products are constructive or destructive, its only proper interest is in establishing truth. The velocity of scientific development in this age is tremendous. In the field in which Francis Amory was interested, God only knows what the next septennium will bring forth, but I can guarantee that it will be good news for sick people, if we can survive the prescriptions of the politicians.

The Amory Committee will welcome nominations for Awards for suitable work done in the current septennium ending in November, 1955.

DISASTER IN CHILE

IN NOVEMBER, 1948, the library of the medical school and the department of parasitology of the Chilean Public Health Service were burned to the ground in a great fire. The scientific equipment, museum specimens, slides, colonies of insects and books and periodicals were completely destroyed. The Department of Parasitology is seeking the cooperation of the scientific world in the task of rehabilitating its collections for the purposes of teaching and research. There is great need of parasitology specimens, mounted or unmounted, histologic sections and insects and arachnids. Medical literature on the subjects of parasitology, biology, public health in general, epidemiology, vital statistics, rural health and health education, including reprints, is urgently needed. A first-class periodical entitled the *Revista chilena de higiene y medicina preventiva* is published at Santiago. The address for the present is Departamento de parasitologia, Cassilla 9183, Santiago, Chile.

The Boston Medical Library, 8 Fenway, Boston 15, in view of the magnitude of this disaster, is prepared to receive literary material, if sent prepaid, and arrange for its transportation to Chile. To avoid duplication, lists of available material should be sent to the Library before shipment.

MASSACHUSETTS MEDICAL SOCIETY

PRINCIPLES AND PROPOSALS

The following principles were adopted on February 9, 1949, by the Committees on Medical Economics and Public Relations of the Massachusetts Medical Society for presentation at the meeting of the Planning Committee of the American Medical Association on February 12, 1949

1 We believe that the health of the people served by prepayment insurance plans will be most benefited by medical care free of government administration and control

2 We should like to call attention to the profligate waste and duplication in health programs operated by the government in regard to both hospital beds and personnel as reported by the Hoover Commission. We believe that compulsory health insurance operated by the Government would result in similar inefficiency

3 We believe that the manner of expression of policy on the part of the American Medical Association has served to diminish public confidence in that body to the serious concern of many of the members of the association

We believe that the policy of the American Medical Association should be one of more active and enthusiastic support of constructive proposals for more equitable distribution of medical care

Therefore, we suggest as constructive proposals worthy of support the following

1 The objective of adequate medical care in our free society is to make available to everyone — regardless of race, color, creed, financial status or place of residence — every known essential preventive, diagnostic and curative medical service of high quality. The attainment of such medical care must necessarily be an evolutionary process which will require the co-operation of all concerned over a period of years

2 The principle of voluntary prepayment health insurance should be the basic method of financing medical care for the large majority of the American people, in order to remove the burden of unpredictable sickness costs and abolish the economic barrier to adequate medical services

3 The success of any plan for medical care is dependent on the mutual co-operation of the public, those rendering professional services and the administrative agencies. This co-operation can be obtained only if those rendering the services are convinced that they will have a continuing authoritative voice in the formulation and execution of policies and plans, thereby assuming their proper share of responsibility

4 Voluntary prepayment group health plans, embodying group practice and providing comprehensive service, when practicable, offer to their members excellent medical care. Hence such plans should be encouraged

5 The people have the right to establish voluntary prepayment plans on any basis guarded by legal restrictions, necessary to assure proper standards and qualifications

6 Provision of adequate medical care for those unable to obtain it by voluntary prepayment plans or by direct payment is the responsibility of the local or state government. Part of the burden of this responsibility may be assumed by charitable agencies. Federal grant-in-aid to state programs administered by state boards of health is an acceptable method of helping to meet this responsibility

7 The medical care of those who are able to purchase it by voluntary prepayment plans or by direct payment is the responsibility of the individual

8 The Federal Government should, wherever possible, support voluntary prepayment programs for hospital and medical care

9 Eligibility for receiving benefits under a program aided by federal grants should be determined by the individual states or communities

10 The patient shall have free choice of his physician, group of physicians, clinic or hospital from among those participating in any plan, provided that the physician, group of physicians, clinic or hospital shall have the right to refuse or accept the patient

11 Physicians and other qualified persons rendering medical care shall receive adequate remuneration for their services

12 The physician shall be free to elect or reject without prejudice participation in a medical care plan. The rights of the physician as to the choice of methods by which he is to be paid shall be fully protected

13 We agree that the federal Government now should subsidize medical and nursing education, medical indigents, health and diagnostic centers, including mental, where not now adequate

We believe effective organizations of state and district health councils would immeasurably improve the community concept of local health needs. The initiative of the people themselves, and especially of the medical and public health personnel, must provide the spark

14 The Massachusetts Medical Society looks upon these basic principles as essential to the development of any successful medical-care plan, and as guides by which to evaluate medical-care plans that may be proposed in

the future, with the understanding that changing conditions may require their later revision

We further urge that our delegates to the American Medical Association be instructed to press for the general adoption of the above principles and proposals by the American Medical Association

H QUIMBY GALLUPE, *Secretary*

grown in numbers and that many more volumes are sent out to hospitals than heretofore. Instead of doctors coming to the Library for books, the books go to the doctor.

We have made some repairs, but more need to be done. The roof has been partially repaired only. There have been some painting jobs done, particularly in the office of the *Journal*, but more bright colors would add considerably and I hope more can be done this year.

In 1950 the Boston Medical Library will be seventy-five years old. It is planned to celebrate its birthday with a dinner at least, and perhaps some other activity. I hope also that a campaign may be started to raise the necessary \$75,000 to complete our much-needed stacks.

I fear I may become tiresome about these stacks but unless they are installed the Library cannot serve its members efficiently. To climb stairs and mount scaffolding to locate volumes in temporary cases is exhausting and takes time. We must soon have the stacks and elevator.

We should continue our effort to increase our fellowships, for, as I have said before, the fellows are the legal corporation of the Library. They are the custodians of its treasures, and the responsibility should rest on many shoulders.

I wish again to express my great appreciation of the work already accomplished by the Librarian and the Director, and I am sure you would wish me to extend your thanks to them also. I want also to thank the Secretary and Treasurer and the members of the Board of Trustees for their whole-hearted co-operation. I think the Treasurer should have a little extra for his several efforts to obtain additional funds. If they come to naught it is certainly no fault of his.

I will leave to the Librarian the pleasant duty of informing you of our recent accessions and of the present state of our collections.

On the whole the prospect looks bright for continued prosperity and usefulness of this collection of books, one of the largest and most valuable medical libraries in the country.

WALTER G. PHIPPEN

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

RETROLENTAL FIBROPLASIA

The National Society for the Prevention of Blindness has circularized directors of maternal and child health with the following material, asking them to bring it to the attention of physicians:

"Retrolental fibroplasia, the presence of an opaque membrane behind the lens, was described by T. L. Terry, of Boston, in 1942 as a cause of blindness among premature infants. In a recent study covering various American cities, the incidence of the

disease in 1301 premature infants weighing less than 1810 gm (4 lb) at birth was 7.6 per cent. It is recommended, therefore, that infants who were below this weight at birth be given a careful ophthalmoscopic examination at the age of six to nine months. Earlier than this the opaque membrane may not be seen except at the extreme periphery of the retina. Ophthalmologists interested in observing the development of the condition may want to see the infants in the early stages to look for dilatation, tortuosity and thickening of the retinal vessels, exudate and evidence of separation of the retina.

"The etiology of retrolental fibroplasia is unknown. Almost all reported cases have occurred in premature infants. Many theories of the causation have been discussed, some relating to the mother's condition during pregnancy, and others relating to nutrition, drug therapy and health of the infant. It is not now believed to be produced by the lights present in incubators.

"Treatment at present is not satisfactory. Some of these babies develop glaucoma and other eye conditions, so that they should be under ophthalmologic supervision."

CONSULTATION CLINICS FOR CRIPPLED CHILDREN IN MASSACHUSETTS

The April schedule for Consultation Clinics for Crippled Children in Massachusetts under the provisions of the Social Security Act follows:

CLINIC	DATE	CLINIC CONSULTANT
Lowell	April 1	Albert H. Brewster
Salem	April 4	Paul W. Hugenberger
Haverhill	April 6	William T. Green
Greenfield	April 11	Charles L. Sturdevant
Gardner	April 12	Carter R. Rowe
Brockton	April 14	George W. Van Gorder
Worcester	April 15	John W. O'Meara
Pittsfield	April 20	Frank A. Slowick
Fall River	April 25	David S. Grice
Springfield	April 26	Garry de N. Hough, Jr.
Hyannis	April 28	Paul L. Norton

Physicians referring new patients to clinics should get in touch with the district health officer to make appointments. Patients are seen by appointment only.

CORRESPONDENCE

DEPRIVATION AND RESTORATION OF LICENSES

To the Editor: At the meeting of the Board of Registration in Medicine held February 17, it was voted to revoke the registrations of Dr. Benedict Kudish, 526 Harvard Street, Brookline, and Dr. Allister F. MacDougall, formerly of Westford, and to restore the registration of Dr. Abraham Freitag.

GEORGE L. SCHADT, M.D., Secretary
Board of Registration in Medicine

DEATHS

BACON — Newton S. Bacon, M.D., of Cambridge, died on March 1. He was in his seventy-seventh year.

Dr. Bacon received his degree from Harvard Medical School in 1899. He was resident physician at Long Island Hospital and was a fellow of the American Medical Association.

A son and a brother survive.

HAND — Edward P. Hand, M.D., of Holyoke, died on January 4. He was in his sixtieth year.

Dr. Hand received his degree from Georgetown University School of Medicine in 1914. He was a former city physician, a member of the staffs of the Holyoke and Providence hospitals and fellow of the American College of Surgeons and American Medical Association.

Three brothers survive.

SKEIRIK — Jibran Y. Skeirik, M.D., of Lawrence, died on December 5. He was in his fifty-fourth year.

Dr. Skeirik received his degree from Harvard Medical School in 1929. He was a fellow of the American Medical Association.

His widow and a daughter survive.

BOSTON MEDICAL LIBRARY

REPORT OF THE PRESIDENT*

At this meeting I complete my term as your president, and it gives me considerable pleasure to present my third annual report on the state of the Library.

When I assumed office it did not take much study to realize that the first great need of the Library was more income. The budget did not balance, and we were drawing heavily on our invested funds, both restricted and unrestricted, to pay current bills. Consequently, economy was the rule, and while the Librarian and the Director did extraordinarily well with a very loyal staff, the service was not so good as might have been expected of a library of our size and reputation. There is, of course, a considerable value in a library building and its contents of books and periodicals, but its real value is in making these books and periodicals available to its members and to the public, in an attractive and prompt way. In other words, the value of a library may be measured in a sense by the circulation of its books and the use of its shelves. This, then, seemed the second objective, to increase the usefulness of the Library.

At the end of three years I am happy to say that the first of these objectives has been attained. When the dilemma in which the Library found itself was clearly presented to the members of the Massachusetts Medical Society, they saw that the Library was a very necessary part of medical education, that its collections should be available to all physicians and, therefore, that it ought to be considered a responsibility of the Society to help promote its efficiency and usefulness. Every fellow of the Mas-

sachusetts Medical Society is now a member of the Library, entitled to its privileges, sharing its responsibility (through its Society-appointed trustees) and contributing to its welfare. This is as it should be. Mr. Conant, speaking of the university library in his annual report, says, "neither teaching nor advanced scholarly studies in the humanities or the social sciences can go forward if a university library suffers from neglect" and I am sure that the same thing is true of medical science and its medical library.

Thanks to this splendid co-operation of the Massachusetts Medical Society the budget is now balanced for the first time in many years. We have paid back a considerable part of our indebtedness to our restricted funds, and with good luck we should be able to clean this up in a year or two at the most. This does not, by any means, put us on easy street. Money must still be saved or raised to complete the much-needed stacks.

Our extra income has enabled us to add several members to our staff, both housekeeping and technical. The extra housekeeping staff has enabled us to apply the mop and duster more efficiently and slowly to clean house. With our extra library staff we have been able to move and sort books that had accumulated in halls, closets and corridors. Some of these have been sold as duplicates, and some put in circulation, and several thousand volumes have been transferred to the Deposit Library on Soldiers Field. We now occupy about two thirds of the space we control in the Deposit Library. This service is rather expensive, but until we can complete the stacks there seems to be no alternative.

Among those added to our staff I might mention Mr. Charles Colby, who comes to us from the Army Medical Library with considerable training and experience in library work. For the present he will have charge of the Reference Room, with special assignments elsewhere as occasion demands and the Director thinks advisable.

I think I can also report considerable progress toward our second objective. In 1945 the use of the Library as measured by circulation was 31,298 volumes. In 1948 it was 53,515, a gain of 22,217 volumes in three years. If measured in terms of attendance the figures are not so dramatic, but even here there was a gain of nearly 3000. Furthermore, it is interesting to note that in 1947, the year before the membership included the fellows of the Massachusetts Medical Society, 9000 nonmembers availed themselves of the privilege of the Library in one way or another. We may therefore say not only that the financial structure of the Library is on a sound foundation but also that its usefulness to the medical profession has been made more available and comprehensive. I think it is fair to say that the smaller increase in attendance compared to the larger growth in circulation is due to the fact that our professional memberships have

SURVIVAL IN PRIMARY CARCINOMA OF THE LUNG*

RICHARD H. OVERHOLT, M.D.,† AND IVAN C. SCHMIDT, M.D.‡

BROOKLINE, MASSACHUSETTS

THE ability to utilize a lung as a unit of excision has made it possible to think in terms of cure when that organ is the primary site of cancer. This state of affairs has existed but for fifteen years,¹⁻⁴ and before that time cancer of the lung was invariably fatal. However new the experience in the surgical management of cancer in this location, a sufficient period has elapsed to permit a fair appraisal of benefits in respect to palliation and cure rates.

During the period in which surgery has been applied for carcinoma of the lung, one of us (R. H. O.) and his associates have examined a total of 604 patients in whom the diagnosis of primary carcinoma of the lung was made. This report is concerned with the ultimate fate of these patients. Survival periods in relation to clinical and operative findings, pathology and the extent of resection are given below. The factor of time between the onset of symptoms and the first request for help and the duration of the period of observation before reference for possible surgical treatment are considered. The necessity of setting ahead the time schedule of discovery by the use of screening methods is discussed.

The recent medical literature contains a number of comprehensive accounts that deal with incidence, symptoms and clinical manifestations of the disease, as well as with technical matters of lung excision.⁵⁻⁸ The over-all problem of cancer of the lung has been particularly well presented by Churchill.⁹ A discussion of clinical features is not included in this report.

MATERIAL

From June, 1932, to August, 1948, a total of 604 patients in whom the diagnosis of primary carcinoma of the lung was made were seen. In 481 cases, the diagnosis was supported by microscopical proof. Great care has been taken to include only cases of carcinoma. Dr. Shields Warren and his associates have again reviewed the histologic sections and have

excluded all cases of so-called "malignant" adenoma, adenoma, lymphoma and all secondary growths. In the unverified group no case was included in which there was reasonable doubt of the diagnosis. It is necessary to consider all cases seen if a true picture of operability and over-all salvage rates is to be obtained.

The sex incidence in this series parallels that in other reported groups. Of the verified cases, 85.8 per cent were in males and 14.2 per cent in females.

OPERABILITY

It has been our practice to advise surgical exploration in all suspected or proved cases with but

‡Fellow in thoracic surgery, Tufts College Medical School.

NOTICES

ANNOUNCEMENTS

Dr Allen G Brailey announces the removal of his office from 1101 to 1180 Beacon Street, Brookline

Dr Robert W Wallace, of Westwood, has assumed the home and practice of Dr George A Small, 81 Walpole Street, Norwood, who has retired from general practice to prepare for the American Board of Anesthesiology

EDWARD K. DUNHAM LECTURES

The Faculty of Medicine of Harvard University has announced that the following lectures on the general topic "The Cerebral Cortex of Man" will be delivered by Dr Wilder Graves Penfield, professor of neurology and neurosurgery, McGill University Faculty of Medicine, and director, Montreal Neurological Institute, under the Edward K Dunham Lectureship for the Promotion of the Medical Sciences

Monday, March 28 Localization of Function

Wednesday, March 30 Ictus Epilepticus (Physiological Observations on the Mechanism of Cerebral Seizures)

Friday, April 1 The Anatomy of Hallucinations, Dreams and Memory

These lectures will be held in the amphitheater of Building D, Harvard Medical School, at 5 p m, on the days indicated

GREATER BOSTON MEDICAL TECHNOLOGISTS

A meeting of the Greater Boston Medical Technologists Association will be held in the operating-room amphitheater of the Children's Hospital, 300 Longwood Avenue, Boston, on March 29 at 8 p m. Dr William Freeman will speak on the subject "The Massachusetts Red Cross Blood Program and How It Affects You"

There will be an announcement about the state conference in April

94TH INFANTRY DIVISION LECTURE

The 94th (Bay State) Infantry Division is sponsoring a series of monthly lectures by prominent physicians in their respective specialties. The second lecture will be held at the Reception Building, Boston State Hospital, Morton and Harvard Streets, Dorchester Center, on Wednesday, March 30, at 8 p m.

Dr Walter E Barton will speak on the subject "Psychiatric Treatment in Hospitals"

All interested physicians, whether reserve officers or not, are cordially invited to attend this carefully planned program. Reserve officers will be given one point credit. Excellent films will also be shown during this period.

BOSTON GASTROENTEROLOGICAL SOCIETY

A meeting of the Boston Gastroenterological Society will be held at 12 noon in the Auditorium of the United States Marine Hospital, 77 Warren Street, Brighton, on Wednesday, April 6. The medical and surgical staffs of the hospital will present unusual medical and surgical gastroenterologic cases.

TUFTS MEDICAL ALUMNI ASSOCIATION
ANNUAL DINNER MEETING

The Tufts Medical Alumni Association will hold its annual dinner meeting at the Hotel Somerset, Boston, on Wednesday, April 6, 1949, at 6:30 p m.

The guest speaker is Dr Leonard A Scheele, surgeon-general of the United States Public Health Service.

Other speakers include Dr Leonard Carmichael, president of Tufts College, and Dr J L Lochner, Jr, secretary, New York State Board of Registration in Medicine. Dr Roy J Heffernan will preside.

The twenty-five-year class will hold its reunion also on this date.

AMERICAN SOCIETY OF ANESTHESIOLOGISTS

A joint meeting of the American Society of Anesthesiologists and the Southeastern Section of the Society will be held at the Statler Hotel, Washington, D C, from April 7 to 9. There will be no registration fee for the meeting.

The program will include lectures, operative clinics at Georgetown and George Washington University hospitals, scientific exhibits, a cocktail party and a banquet.

NEW ENGLAND SOCIETY OF
ANESTHESIOLOGISTS

A meeting of the New England Society of Anesthesiologists will be held in the auditorium of Building A, Boston University School of Medicine, 80 East Concord Street, Boston, on Tuesday, April 12, at 8 p m. The scientific program will consist of the following:

Pharmacological Factors Influencing Collateral Respiration. Possible relation to the etiology of pulmonary complications. Ralph D Alley, M D, of the Department of Surgery, Yale University School of Medicine.

Pulmonary Ventilatory and Respiratory Function Determination Methods. Donald Rayl, M D, resident in surgery; Uncas-on-Thames (Norwich State Tuberculosis Sanatorium), Norwich, Connecticut.

Artificial Respiration by Electrical Stimulation of the Phrenic Nerves. Demonstration by Stanley Sarnoff, M D, of the Harvard Medical School Department of Applied Physiology.

Physicians and medical students are invited.

AMERICAN COLLEGE OF CHEST PHYSICIANS

The Board of Examiners of the American College of Chest Physicians announces that the next oral and written examinations for fellowship will be held in Atlantic City on June 2, 1949. Candidates for fellowship in the College who would like to take the examinations should communicate with the executive secretary, American College of Chest Physicians, 500 North Dearborn Street, Chicago 10, Illinois.

The fifteenth annual meeting of the College will be held at the Ambassador Hotel, Atlantic City, from June 2 to 5. An interesting scientific program has been arranged for this meeting, and speakers from several countries are scheduled to appear.

AMERICAN ASSOCIATION OF
RAILWAY SURGEONS

The sixty-first annual meeting of the American Association of Railway Surgeons will be held at the Drake Hotel, Chicago, on Thursday, June 30, Friday, July 1, and Saturday morning, July 2.

An exceptionally interesting and instructive scientific program will be given from 10:00 to 12:30 on each of the three mornings, and from 2:00 to 4:30 on the first two afternoons.

The morning sessions will include twelve papers on various medical and surgical subjects, presented by outstanding authorities. The two afternoon sessions will be devoted to symposiums on "Lesions of the Bones and Joints" and "Intra-thoracic Disorders."

The annual dinner will be held at the Drake Hotel on Friday evening, July 1.

Room reservations may be made at the Drake Hotel or at the nearby Knickerbocker Hotel.

There will be a technical exhibit in conjunction with the scientific meetings.

(Notices concluded on page xiii)

Figure 1 shows the survival periods of all patients who submitted to pulmonary resection. It will be seen that of the patients operated upon within the past year, 60 per cent are still alive with 8 late deaths and 8 operative deaths. Of those operated upon five years or more ago, 24.4 per cent are still alive (10 patients).

An analysis of the survival periods in the cases without extension is shown in Figure 2. It will be seen that of 11 patients operated upon in the past year, there was 1 operative death, and all the rest are still living. Sixteen patients are living more than a year, 14 more than two years, 12 more than three years, 9 more than four years, and 8 more than five years after operation.

If operative deaths are excluded, 10 patients, or 100 per cent of those who survived operation within the past year, are still living, whereas 8 (50 per cent)

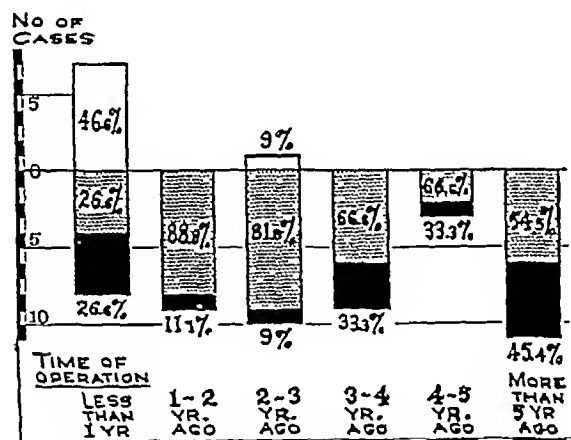

FIGURE 4 Survival after Resection in 50 Cases with Gross Extension

of those who survived operation five or more years ago are still alive.

The average duration of life of those who died postoperatively (excluding hospital deaths) was eleven and one-tenth months. Of these, none lived longer than twenty-eight months.

Cases in which there was lymph-node extension only are shown in Figure 3. In the majority of these cases the lymph nodes were found to be involved as a result of microscopical study, but in the few cases in which the glands were grossly involved, all tumor tissue was thought to have been removed. As can be seen from the chart, 8 of 28 patients are alive more than two years and 2 of 10 are alive five years or more after operation. Of the late deaths, the average duration of life was nine and three-fifths months. Of these, no patient lived longer than twenty-three months.

The group in which there was gross extension is shown in Figure 4. There were 34 cases in this group

in which a palliative resection was done — that is, one in which gross tumor tissue was left behind. In the remaining 24 cases, gross extension was encountered, but all detectable tumor tissue was removed. This group includes the following cases in which there was invasion of the ribs or chest wall, cases in which there was mediastinal invasion, including those in which there was invasion of the pericardium, and cases in which there was invasion of the diaphragm. In all, the invasion was apparent on gross examination, as distinguished from the lymphatic metastases of the preceding group.

Of 43 patients in this category operated upon more than a year ago, only 1 is alive. This man has an epidermoid carcinoma (Grade II) and has lived

TABLE 3 Survival Periods from Diagnosis to Death from Disease in Cases of Primary Carcinoma of the Lung

TREATMENT	NO. OF CASES	SURVIVAL
None	148	4 4
Exploration	102	7 0
Resection		
Gross extension	30	10 0
Lymph nodes involved	22	9 6
No apparent extension	19	11 1

more than two years. His was a palliative resection in which gross tumor was left behind, so that there is no possibility of cure. All the other 7 survivors were operated upon less than a year ago. In this group, the average life of those who died postoperatively was ten months, excluding hospital deaths. The longest survivor lived twenty-nine months. This experience indicates that the prognosis is poor if gross extension has occurred, even if all detectable tumor is removed. We have been agreeably surprised at the number of survivors in the group with lymph-node extension. Other reports from the literature bearing upon this subject are few. Ochsner, DeBakey and Dixon⁷ reported that in their series of cases with either lymph-node or gross extension only 2 of 27 patients in this combined group survived beyond a three-year period, and none beyond six years. Coleman¹⁰ reported the cures of 2 patients still living two and six years respectively after resection in which the tumor had invaded the ribs. In our own series there were 6 cases, but no patient has survived more than twenty-seven months.

SURVIVAL IN RELATION TO TYPE OF PROCEDURE

The vast majority of patients in our resection series have been treated by pneumonectomy. Only by mass removal of the lung can all hilar lymph nodes be resected, and mediastinal dissection is

Of all cases, 48 per cent were explored, and resection was carried out in 27 per cent. In recent years, there has been an encouraging trend toward higher rates of operability, and in the past five years, 51 per cent of all cases seen have been explored and 32 per cent resected.

In Table 1 and 2 and Figure 2, 3 and 4 the resections are divided into three categories according to the extent of the lesion: patients with no demon-

strated extension, patients in whom all tumor was thought to have been removed (candidates for cure if all tumor is re-

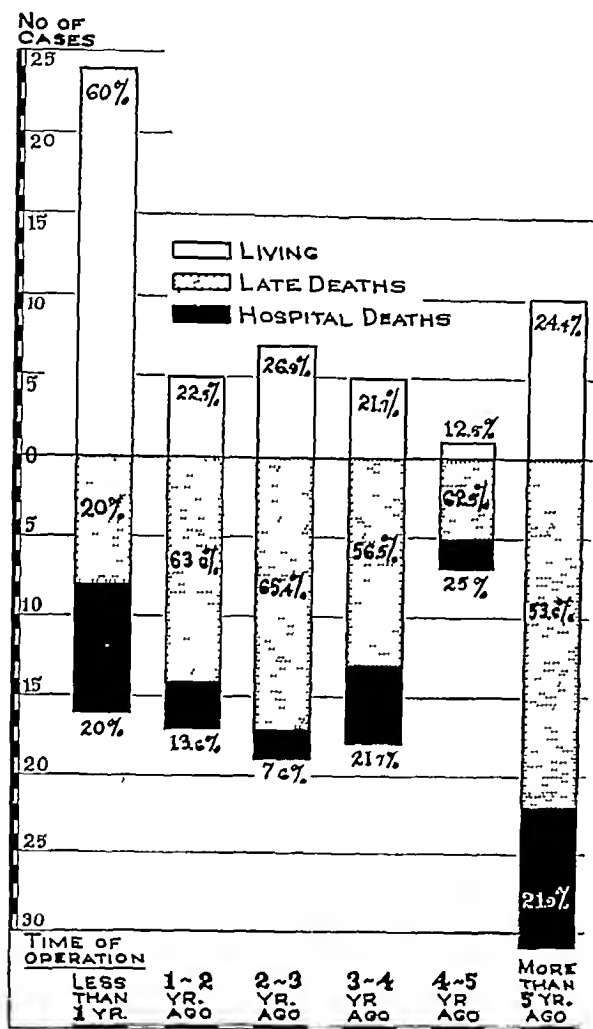

FIGURE 1 Survival in Total of 102 Patients who Submitted to Resection

There were 29 operative deaths, 2 patients who could not be followed, 3 who died of causes other than recurrent cancer, and 2 epidermoid carcinomas that were not graded (leaving a total of 126 cases, which are considered in the succeeding figures)

strable extrapulmonary extension (these are the best candidates for cure), those with lymph-node metastases only, the regional lymph nodes being grossly involved in some and the metastases being found on microscopical examination in others (candidates for possible cure if the excised nodes represented the sole metastatic process), and those with gross evidence of extension, in turn divided into pa-

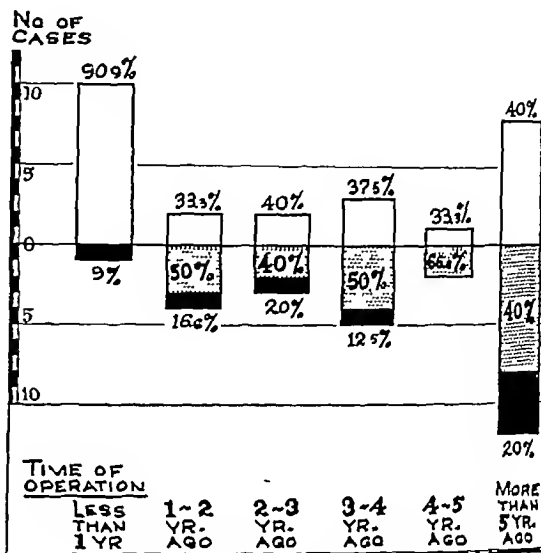

FIGURE 2 Survival after Resection in 56 Cases without Extension

moved) and those in whom gross tumor was left behind (palliative procedure only)

SURVIVAL PERIODS

The survival periods of patients who were known to have died from their disease are shown in Table 3

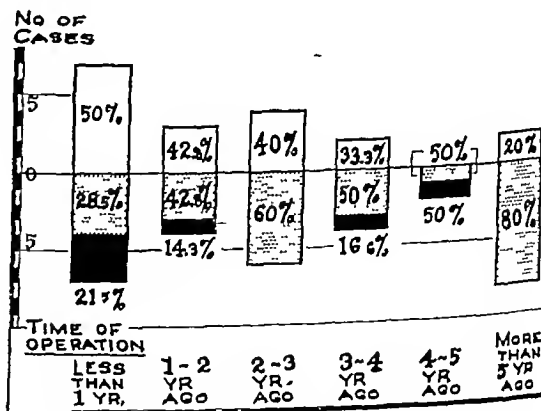

FIGURE 3 Survival after Resection in 49 Cases with Lymph Node Extension Only

In cases in which the cancer was obviously out of bounds and in which no surgical treatment was offered the patients lived an average of four and two-fifths months. At the other end was a group of 19 patients submitted to resection in whom the growth apparently was localized but who subsequently died of their disease. The average survival of this group was eleven and three-tenths months.

without apparent extension of any kind. The patients surviving for three and two years both had lymph-node metastases. Of those who died, 4 had gross extension, and 2 had lymph-node metastases, the average survival was fifteen and one-tenth

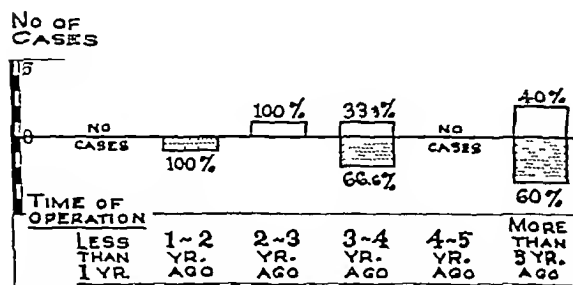

FIGURE 8 Survival after Resection in 10 Cases of Epidermoid Carcinoma (Grade I)

months, and yet no patient lived more than twenty-seven months.

In the cases of epidermoid carcinoma (Grade II) there were 36 patients, of whom 20 still survive, 8 of 18 having lived longer than three years, and 5 of 10 having lived longer than five years (Fig 9). In 3 of 5 cases in which there was no extension of

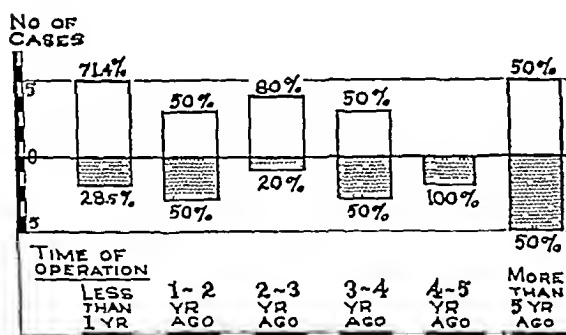

FIGURE 9 Survival after Resection in 36 Cases of Epidermoid Carcinoma (Grade II)

the tumor the patients have survived five years or more after operation, and 5 of 9 patients in this same group have survived three years or more. Two of 5 patients with lymph-node metastases are still living five years or more, and 3 of 8 cases are living three years or more after operation. No patient who died lived longer than twenty-four months, and the average survival was twelve and nine-tenths months.

Of 33 cases in the group diagnosed epidermoid carcinoma (Grade III), 3 of 6 patients operated upon five years or more ago and 4 of 8 operated upon more than four years ago still survive (Fig 10). However, there are no survivors among the patients operated on three, two and one years

ago. Of those operated upon more than four years ago, the 4 survivors were in the group without extension of the tumor. In the intervening years, however, 3 other patients without extension have died. Four patients with lymph-node extension upon whom operation was performed more than a year ago have all died, as have 6 with gross extension. The average duration of life in the late deaths was eight and two-fifths months, and no patient lived longer than twenty-eight months.

SYMPTOMS AND SURVIVAL

All patients submitted to resection were divided into three groups: those who had symptoms for less

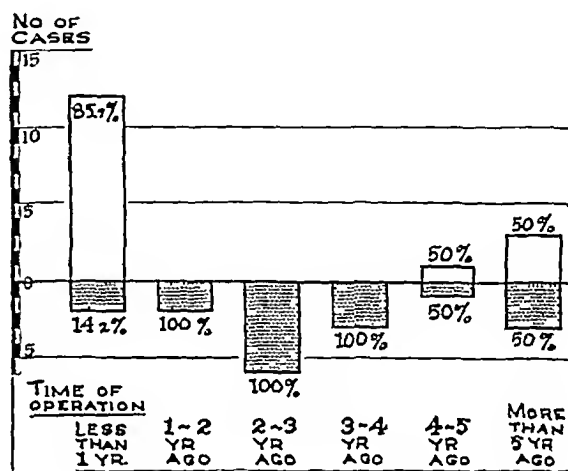

FIGURE 10 Survival after Resection in 33 Cases of Epidermoid Carcinoma (Grade III)

than six months, those with symptoms for six to twelve months, and those with symptoms for more than a year. One would expect to find a higher number of survivors in those patients who had symptoms for less than six months, and yet it was found that in this group the percentage of survivors was lower than that in patients who had symptoms for six to twelve months. The percentage of survivors of those who had symptoms for more than a year was about the same as that in patients who had symptoms for less than six months. This finding could be interpreted to mean that many growths are relatively far advanced by the time symptoms develop. No attempt was made, however, to correlate pathology with the duration of symptoms. Many patients with anaplastic tumors presented themselves before they had had symptoms for a year, whereas others with more slowly growing tumors waited longer before consulting a physician.

Those patients who survived for more than five years are shown in Table 4. All were treated by total pneumonectomy. Of these, 5 are well, 2 are reasonably well, and the last available information concerning another revealed that she was well in

facilitated. Occasionally, however, in a patient of advanced age or one with a narrow respiratory reserve who has a peripheral tumor, lobectomy may be preferable. This is particularly true if there is positive evidence of gross extrapulmonary extension. Palliative lobectomy was performed upon a few patients who had peripheral tumors with invasion of the chest wall that could not be totally resected. However, it has been found that these procedures are rarely satisfactory in relieving pain even if coupled with division of the intercostal nerves. Treatment by rhizotomy, high chordotomy or frontal lobotomy if the pain is severe should receive consideration. Lobectomy was performed on 8 patients in our series, 4 of whom were operated upon more than two years ago, and all these are dead. Four patients treated by lobectomy within the past two years are still living.

PATHOLOGY IN RELATION TO SURVIVAL

The pathological cell type is second only to the extension of the tumor in determining survival. The pathologist has divided all the pathologic cell types into three major classifications: undifferentiated carcinoma, carcinoma arising from glandular epithelium, including adenocarcinoma and carcinoma

with lymph-node metastases only, and 2 with gross extension. The surviving patient had no demonstrable extension at the time of operation. The average duration of life of those who died was ten and two-tenths months, and of this group, none lived longer than twenty-seven months.

There were 10 cases in which carcinoma simplex was diagnosed (Fig 7). None of the patients

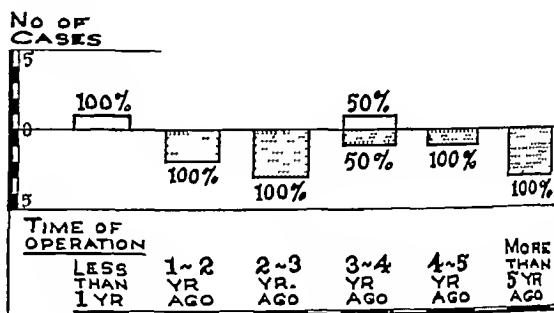

FIGURE 6 Survival after Resection in 12 Cases of Adenocarcinoma

operated upon more than a year ago are still alive. Only 1 of 3 patients operated upon within the past year is still alive. In this entire group, there were 3 cases in which there was no apparent extension, 4 in which there was lymph-node metastasis only, and 3 in which there was gross extension. The average

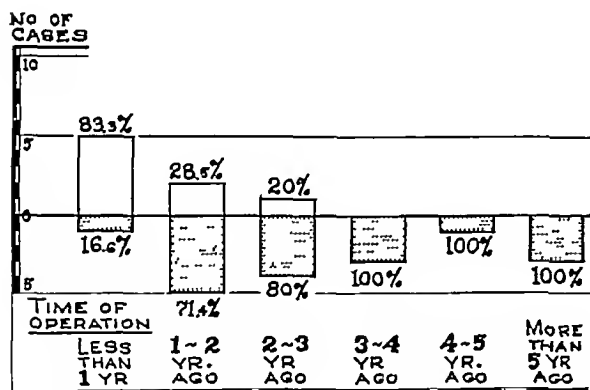

FIGURE 5 Survival after Resection in 25 Cases of Undifferentiated Carcinoma

simplex, and epidermoid carcinoma, including sub-groupings Grades I, II and III.

Only those who survived operation are considered.

In the undifferentiated group (Fig 5), there were 25 cases. There was no apparent extension of the tumor in 4 of the 7 patients operated upon more than three years ago, and yet none are living. In the late deaths, no patient lived longer than twenty-nine months, and the average duration of life of those who died was nine and three-tenths months.

In the adenocarcinoma group (Fig 6), there were 12 cases. Of the 6 patients upon whom operation was performed more than three years previously, it will be seen that only 1 patient has survived. In this group of 6 cases, there were 3 without extension, 1

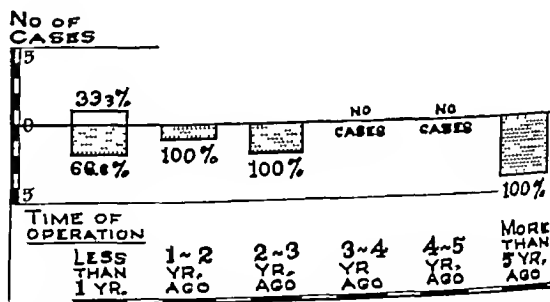

FIGURE 7 Survival after Resection in 10 Cases of Carcinoma Simplex

duration of life of patients who died was seven and three-tenths months, and none lived longer than thirteen months.

The final group to be considered in relation to survival to pathological type is that in which the diagnosis was epidermoid carcinoma, and it is in these cases that the prognosis is most favorable.

In cases diagnosed as Grade I (Fig 8) there were 10 cases. It will be seen that 4 of these patients are still living more than two years, 3 of 8 patients more than three years, and 2 of 5 patients living more than five years after operation. The 2 patients living more than five years after operation were both in the group

bronchoscopy or even exploratory thoracotomy may be necessary to settle the diagnosis

Efforts to discover primary carcinoma of the lung in its silent and early stage will be rewarded. The risk of resection is reasonably low and is constantly being lowered. Five-year survival rates for patients treated at a time when the growth was apparently localized have been high

SUMMARY

Statistics bearing upon operability and survival of 604 patients in whom the diagnosis of primary carcinoma of the lung was made are presented

The extension or localization of the lesion and the pathological cell type are the most important factors in survival after resection

With known and available methods of screening for silent lesions, a significant increase in the salvage rate in primary cancer of the lung should be possible

In the identical period of the above study (1932-1948), 27 patients were treated by pulmonary resections for tumors diagnosed as bronchial adenoma, infiltrative bronchial adenoma or malignant adenoma. Some authors consider these tumors to be primary carcinomas (adenocarcinoma, Grade I) and include them in their cancer statistics. From a clinical point of view, they should receive special consideration. For example, 26 of 27 patients have been followed recently, and there has been only 1 late death. This patient died of a metastasis that had similar characteristics to the

bronchial tumor. One patient has not been followed. Ten of the remaining 25 patients have lived five to fifteen and a half years after operation. In the adenoma series, there were no operative deaths; therefore, since immediate and late results are so totally different in the "so-called" adenoma group, we have not included them in the above paper on true cancer of the lung

PULMONARY EMBOLISM*

Analysis of 74 Autopsy Cases Since 1941

KLAUS DEHLINGER, M.D.,† AND PAUL RIEMENSCHNEIDER, M.D.‡

BOSTON

THERE has been no significant decrease in the percentage of cases in which pulmonary emboli were demonstrated at autopsy at this hospital group since the introduction of definitive and prophylactic treatment of venous thrombosis. This therapy includes venous interruption and the administration of heparin and dicumarol, as well as prophylactic exercises, early ambulation and even paravertebral autonomic block in one case. During the thirteen years from 1928 through 1940 pulmonary emboli were found in 75 per cent of all autopsies, whereas the figure became 67 per cent during the following six-year period (Table 1). The percentage of operations that were followed by pulmonary embolism, as found at post-mortem examination, has decreased somewhat more in the same intervals. Before January, 1941, the figure was 0.13 per cent, since that date it has dropped to 0.09

per cent, but even this decrease is not definitely significant statistically. ‡

Because there are so many factors that may change over a period of years, making statistical data questionable, Table 2 was compiled. It shows the various relations between the number of hospital admissions, operations, deaths, autopsies and pulmonary-embolism autopsies per year since 1928. The ratio of operations to hospital admissions has gradually increased over the years. We feel safe in concluding that the other individual ratios have not changed enough to make the above percentages on pulmonary embolism at autopsy lose their significance.

*The standard error of the difference for the percentages was calculated according to the formula given in Arkin and Cotton.¹ The actual difference between the two figures (74.75-66.55=0.790) is only 0.22 times the standard error of the difference (3.534). This is definitely not significant, for the chances are more than eight out of ten that the actual difference is an accidental one.

Using the same formula for the percentage of operations followed by embolism as that found at autopsy for the same groups of years, we find that the actual difference between the two (0.0412 per cent) is 2.5 times the standard error of the difference (0.0177 per cent) which may be significant.

*From the Laboratory of Pathology of the New England Deaconess and New England Baptist hospitals.

†Resident in radiology, Peter Bent Brigham Hospital formerly, assistant resident in pathology, New England Deaconess Hospital.

1947 Of the 2 remaining patients, 1 was well for ten years but has gone downhill in the past two years and is now a respiratory invalid, the other was well for five years and has had a similar downhill course in the past two years. Both are apparently free of cancer but are suffering from a lack of respiratory reserve.

In the group of patients operated upon more than five years ago, there is an additional patient who died in an accident thirty-nine months after resection. He was working every day until his death, and was apparently free of disease. He pre-

histories of patients seen in 1947 and 1948 showed that the interval between the first symptom and the date of diagnosis had been reduced only to ten months. The average patient delayed seeing a doctor for three and eight-tenths months. The first x-ray film was ordered one and six-tenths months later, compared with an interval of three months in the earlier group. However, the diagnosis was not established until four and six-tenths months later.

The interval between onset of symptoms and diagnosis will have to be shortened, in fact, this

TABLE 4 *Results in Patients Who Have Survived Five or More Years after Pulmonary Resection for Carcinoma of the Lung*

CASE NO	DATE OF OPERATION	AGE	SEX	FINAL DIAGNOSIS	PRESENT STATUS
1	3/13/36	yr 45	M	Epidermoid carcinoma (Grade II)	Patient well for 10 years downhill in past 2 years, now respiratory invalid.
2	6/10/37	45	F	Epidermoid carcinoma (Grade III)	According to last information (1947) patient well
3	3/18/41	44	M	Epidermoid carcinoma (Grade III)	Patient well for 5 years downhill in past 2 years now respiratory invalid.
4	10/11/41	43	M	Epidermoid carcinoma (Grade I)	Patient well does light work some dyspnea upon exertion only
5	5/7/42	36	M	Epidermoid carcinoma (Grade II)	Patient well
6	4/16/42	48	M	Epidermoid carcinoma (Grade II)	Patient well works every day some dyspnea upon exertion only
7	7/31/42	48	M	Epidermoid carcinoma (Grade I)	Patient fairly well does light work, uses easily
8	8/28/42	54	M	Epidermoid carcinoma (Grade II)	Patient well

10	7/13/43	55	M	Epidermoid carcinoma (Grade III)	Patient well

sumably had been cured, for in our entire series no patient who later died of his disease has lived longer than thirty months after diagnosis. This includes untreated patients, those in whom thoracotomy only was performed, and those who had pulmonary resection. All who died had signs and symptoms of cancer for several months prior to death, so that it appears from our experience that any patient who lives thirty months or more without symptoms of recurrence has an excellent chance for cure.

FUTURE POSSIBILITIES

The present method of waiting for symptoms, followed by the delay that seems to be necessary to work out the differential diagnosis, has not produced the results that we believe are possible in the present-day surgical treatment of primary carcinoma of the lung.

It was previously pointed out that an analysis of the histories of 133 patients seen between 1932 and 1942 revealed that there was an average interval of eleven and three-fourths months between the first symptom and the establishment of the diagnosis.¹¹ The average patient delayed seeing a doctor for three months. The first x-ray examination was not ordered until another three months had elapsed. The diagnosis was established five and three-fourths months later. A review of the

interval can be eliminated altogether. The growth can be discovered before it is large enough to produce symptoms. Radiologic screening of the population, now being employed in uncovering cases of silent tuberculosis, can be further extended. Older age groups should be included, and the screening should be repeated each year. Early carcinomas usually produce changes in the x-ray picture that can be detected by the experienced observer, even if the tumor itself will not cast a shadow. Approximately 80 per cent of the lesions are situated in a lobar or segmental bronchus, and the secondary changes in the corresponding segment or lobe, incident to partial or total bronchial occlusion, cast abnormal shadows detectable in the miniature film used for screening. There is a period during the growth of the tumor when abnormal x-ray densities develop and then symptoms appear. Part of this period of silent growth can be saved. The minority group of peripheral tumors cast direct shadows, which, even in their early stages, should be caught in the screening process owing to the highly rarefied normal lung field. If abnormal densities are discovered, they will require proper identification without delay. Additional x-ray studies should be arranged for immediately. Cytologic examination of the sputum and of material aspirated from the bronchi (Papanicolaou technic),

bronchoscopy or even exploratory thoracotomy may be necessary to settle the diagnosis

Efforts to discover primary carcinoma of the lung in its silent and early stage will be rewarded. The risk of resection is reasonably low and is constantly being lowered. Five-year survival rates for patients treated at a time when the growth was apparently localized have been high.

embolism as the primary cause of death to be ten and a third years older than the average age of the patient at operation

The immediate cause of death in these cases has changed somewhat through the years. In the recent six-year group of 74 cases, embolism was considered the immediate cause in 58. The other causes were as follows: cardiac infarction 3, cardiac failure 3, pulmonary insufficiency 2, pulmonary edema 1, sepsis 2, peritonitis 1, and undetermined 4 cases. It will be noted that only 3 were ascribed to infection. Again, with the first 74 cases since 1928 for

patient who lived only thirty-three hours post-operatively had no recognized symptoms of thrombosis before the surgical procedure. These time relations are in accord with other data in the literature, which include many more cases and have been reviewed by Neuhof and Klein.²

Conclusions regarding the primary sites of the thrombi have been divergent in the literature. Some claim that almost all thrombi arise in the tributaries of the common femoral vein. On the other hand, Moran⁹ found that 45 per cent of all male patients who died with pulmonary emboli had prostatic

TABLE 3 Comparison of Recent and Remote Autopsied Cases of Pulmonary Embolism

PERIOD	ARITHMETIC MEAN AGE	DEATHS DIRECTLY ATTRIBUTABLE TO EMBOLISM	DEATHS DIRECTLY ATTRIBUTABLE TO INFECTION	PATIENTS OPERATED ON	PATIENTS NOT OPERATED ON
1941-1946 (74 cases)	57 60.0	58	3	53	21
1928-1940 (74 cases)	58.1	48	11	50	24

comparison (Table 3) pulmonary embolism was considered the immediate cause of death in 48, whereas infection accounted for 11. Because infection is now controllable to a great extent, embolism as the immediate cause of death has become in recent years relatively more rather than less common in this series.

The role of surgery as a causative factor in thromboembolic disease is difficult to evaluate. In the early literature it was especially stressed, but more recently it has been shown that a greater percentage of medical patients than of those subjected to surgery die of pulmonary embolism.^{6,7} In the recent series, 72 per cent (53 patients) underwent operations. This is approximately the percentage of surgical cases in this group of hospitals. It is, however, the group of 21 patients not operated upon that are especially worthy of consideration. Only 5 had mural thrombi in the heart, 2 of these also had leg thrombi. Thus, 16 to 18 of 21 patients who were not operated on died with pulmonary emboli originating from veins rather than from the endocardium. These figures substantiate the views of Hunter et al.⁸ that the common denominator of hospitalized medical and surgical patients is confinement to bed irrespective of the type of disease, and that therefore recumbency is probably the greatest single factor in thrombus formation.

The duration of bed rest in this group cannot be determined, for it is not known how long the patients had been in bed before entering the hospital or undergoing surgery. However, the interval from operation to death in patients who underwent a single recent operation is known (Fig 1). The time extremes are thirty-three hours and thirty-six days, with an arithmetic mean of twelve days. The

thrombi. In 96 patients who died because of a massive embolus Cohn and Walsh¹⁰ found thrombi in 31 of the femoral or iliac veins, 20 in the pelvic veins (14 periprostatic), 4 in the tributaries of the superior vena cava and 7 in the right side of the heart, and in 37 no thrombus was found. Our figures were similar. In reviewing these figures one must keep in mind that with a changing resident staff in

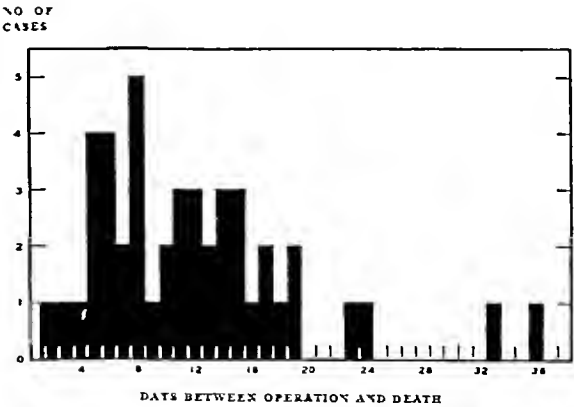

FIGURE 1 Interval between Operation and Death in Patients Undergoing a Single Operation

pathology the interest in this problem has waxed and waned so that the primary site of thrombus was searched for with varying degrees of diligence. In Neuhof's² series, for example, no primary thrombus was found in over 50 per cent of the cases.

We classified the primary sites of thrombi into three groups according to the probable value of interruption of the common femoral vein (Fig 2). The procedure was considered helpful, valueless or questionably helpful (Table 4). The first group

The purpose of this study is to attempt to determine why many patients are still dying with pulmonary embolism despite the availability of anticoagulant drugs and the general use of venous interruption in recent years. No analysis of the numerous successfully treated cases was made. Hence this report should not be considered in any

ing data can be obtained. Some of these cases have been previously reported in a different type of study by Evans.⁴

There were 41 men and 33 women. Most authors on the subject agree that there is no sex difference, except possibly that the pelvic venous plexuses are more often disturbed surgically in the female, and

excellently done by Neuhof and Klein² and Homans.³

Seventy-four consecutive autopsy cases with pulmonary embolism in the six-year period from 1941 through 1946 have been studied. Breakdown of so small a number of cases cannot be expected to give statistically significant results, but interest-

the ages for the first 74 autopsied cases with pulmonary embolism since 1928 was found to be slightly over fifty-eight years. Thus, there is even less than twenty-four months' difference between the average ages of the two groups. It is of interest that Henderson⁵ found the average age in 223 patients dying after operation with pulmonary

monary infarction was the sole pathologic finding in the lungs at autopsy. Chest roentgenograms of 5 of these showed no abnormal densities in the lung fields, so that in all probability the emboli lodged in the pulmonary arteries after the film was taken. In the remaining 5 cases, the greatest misinterpretation of shadows cast by lung infarcts as the only pathologic process found at autopsy was the diagnosis of pneumonitis or bronchopneumonia (4 cases).

Since 1941 the clinicians at this group of hospitals have been actively treating patients to prevent pulmonary emboli. The Lahey Clinic alone treated 184 postoperative cases of venous thrombosis with or without pulmonary embolism from 1942 through 1946. In these only 3 patients died of thromboembolic disease.¹¹ Yet the most surprising result of our study was that in the 74 autopsied cases only 5 patients had received any definitive treatment to prevent embolism. This emphasizes the difficulty in recognizing venous thrombosis and benign pulmonary embolism. Three of these patients died with embolism as the immediate cause of death. The other 2 died of unrelated conditions, and the minor emboli were incidental findings.

Thus, despite the many enthusiastic reports on venous interruption and anticoagulant therapy for the prevention of pulmonary embolism, the problem is still far from solved, and the careful search for the slightest symptoms suggestive of venous thrombosis and pulmonary embolism remains a most important responsibility of every physician.

SUMMARY

The incidence of autopsied cases with demonstrable pulmonary embolism has dropped only from 7.5 to 6.7 per cent since the use of definitive and prophylactic treatment of venous thrombosis, including venous interruption and the administration of heparin and dicumarol.

The decrease is slightly greater when the percentage of deaths coming to autopsy with pulmonary

emboli is compared to the number of operations performed, rather than to the total number of autopsies done. From 1928 through 1940 it was 0.13 per cent, whereas from 1941 through 1946 it was 0.09 per cent. From a statistical standpoint this might be a significant decrease.

A study of the 74 cases autopsied from 1941 through 1946 was undertaken to help explain this relatively insignificant change. The cases were analyzed according to age, sex, immediate cause of death, primary site of thrombus, medical versus surgical status and preventive therapy.

In only 5 of the 74 autopsied cases of pulmonary emboli did the patients receive specific therapy for the prevention of embolism. This suggests that the primary problem is the difficulty in the diagnosis of venous thrombosis and nonfatal pulmonary embolism.

Despite the availability of various means of preventing pulmonary embolism, the condition remains a great problem.

comprises 15 cases in which femoral-vein ligation was considered helpful, in each, a thrombus was found in the veins below the inguinal ligament. The second group consists of 15 cases in which

cases in which the procedure might have been helpful if it had been performed early enough, it includes the cases in which a thrombus was found in the veins collecting blood from the femoral vein but was proximal to the inguinal ligament—namely, the external iliac, common iliac and inferior vena cava—as well as the 25 cases in which no primary thrombus was found. These figures lead us to conclude that interruption of the common femoral vein is not the ideal approach to the prevention of embolic phenomena.

The greatest problem of all, however, is still the difficulty in recognizing venous thrombosis and benign pulmonary embolism before further embolism results in death. In many of the charts in these 74 cases no evidence of venous thrombosis was given, except possibly a slight rise in pulse and temperature. In other cases, however, the patient had chest symptoms that were diagnosed as pneumonitis, pulmonary edema, atelectasis and coronary thrombosis and remained unrecognized as embolic episodes until death. Evans⁴ found in retrospect that 85 per cent of 52 postoperative fatal cases had premonitory signs and symptoms for a sufficiently long time before fatal embolism to have allowed adequate therapy to have been administered.

Roentgenograms are not so helpful as one might think. In only 28 of the 74 fatal cases were there sufficient chest symptoms during the last week of life before the final agonal episode to warrant x-ray examination of the chest. In 18 of these 28 cases pulmonary embolism was not recognized radiographically because of additional coexistent pulmonary and pleural abnormalities as shown by autopsy. These included pulmonary cancer in 4 cases, pulmonary congestion in 3, pneumonitis in 2, and atelectasis, pneumonitis and atelectasis, lung

endocardium of the right side of the heart, fatal pulmonary emboli could probably have been prevented in 9 of these by tying off of the inferior vena cava. The third group contains the remaining 44

abscess, chronic empyema, fibrous pleural adhesions and effusion with pneumothorax in 1 each. This leaves only 10 cases with x-ray films available in which pulmonary embolism with or without pul-

of 9 millimols per liter and a serum potassium of 4.43 milliequiv per liter. Treatment, which was immediately instituted, consisted of 3 liters of physiologic saline solution and 450 units of regular insulin. The lowest serum potassium, which was determined 20 hours after admission, was 3.6 milliequiv per liter.

CASE 5 A young adult in mild acidosis had a carbon dioxide content of 10 millimols per liter and a blood sugar of 296 mg per 100 cc. This patient required only 165 units of regular insulin, and the serum potassium fell from a normal of 4.3 to only 4.1 milliequiv per liter.

CASE 6 An elderly woman with known diabetes who had never required insulin was found comatose in her apartment after approximately 24 hours of acidosis. After hospitalization and institution of treatment she responded to 340 units of insulin and roused from her coma. She continued anuric, however, and suddenly vomited and aspirated a large amount of material in spite of previous gastric lavage. Death was due to asphyxia.

DISCUSSION

The cause of low serum potassium levels may be contrasted with those of high values, which occur almost without exception in patients with oliguria

on admission. The period of early recovery from coma may indeed be one of the most dangerous periods from a chemical standpoint. Thus, the serum potassium levels in Cases 2 and 6, which were slightly elevated on admission, fell to below the normal range in a period of four to twenty-four hours after recovery from coma. This factor makes imperative the early feeding by mouth of orange juice and other foods rich in potassium.

Various aspects of emergency serum potassium levels in diabetic coma are presented in Table 2. The diagnosis of low serum potassium is particularly to be borne in mind when a patient in diabetic coma has received glucose solution by vein early, and, at a period varying from four to twenty-four hours after the beginning of treatment, shows the characteristic clinical signs. So far, no patient in this series (or in other reports from the literature) who has not received considerable amounts of glu-

TABLE 2 *Emergency Serum Potassium Levels in Diabetic Coma*

POTASSIUM LEVEL	CAUSES	DIAGNOSTIC FEATURES	TREATMENT	PREVENTION
Low	Insufficient or delayed treatment of acidosis; extreme diuresis with loss of potassium in urine; excessive administration of glucose, with glycogen deposition vomiting	Sudden flaccid paralysis progressing to respiratory paralysis 10-24 hr after treatment with glucose and insulin; fish mouth facial expression; low-voltage QRS complexes and flat or inverted T waves fall in serum potassium from normal of 4.1 to 5.6 milliequiv per liter to less than 3.0 milliequiv	Potassium phosphate (2 gm.) with potassium dihydrogen phosphate (0.4 gm.) intravenously 100 cc of 2 per cent potassium chloride solution intravenously	Withholding of glucose from patients in coma; rapid treatment to shorten acidosis; early feeding of potassium-containing food (oatmeal, orange juice and so forth)
High	Oliguria or anuria; administration of potassium in acute or chronic renal failure	Paralysis (flaccid) or spastic type; absent P waves; wide QRS complexes and high peaked T waves; high value for serum potassium (levels exceeding 12 milliequiv per liter may be fatal)	Case should be treated; administration of glucose and insulin	No administration of potassium (without sure indication)

or anuria. Cases 2 and 6 in this series illustrate this point well. Each patient was anuric for a variable period before treatment, and in each, the admission potassium level was slightly above normal limits. As early as 1915, Smillie⁶ described potassium poisoning in nephritis when potassium salts were administered therapeutically. Van Slyke⁷ points out that a fall in systolic blood pressure of 40 to 60 may in itself be sufficient to cause anuria. Such levels are not at all rare in severe diabetic coma. It should be recalled, however, that elevated serum potassium levels in diabetic acidosis and shock do not necessarily reflect the true state of the tissue cells of the body. Prior to the late stage of anuria and hemoconcentration, there is usually a prolonged period of diuresis with resultant potassium loss. Thus, the ambiguous condition results in which there is a total body deficit of potassium in the presence of an elevated serum potassium level. This condition must be borne in mind during treatment, and a false sense of security avoided when one finds a normal or slightly elevated level

during the first few hours of treatment has shown seriously low serum potassium levels. The actual diagnosis is, of course, best established by serial analyses of the serum. Since this determination is not always obtainable, however, one should always remember that (in patients with low serum potassium levels) the sudden development of marked muscular weakness or actual flaccid paralysis may mean hypopotassemia. In 1 or 2 patients a peculiar fish-mouth facial expression has been noted. An important diagnostic aid is afforded by the electrocardiogram, in which the changes accompanying low serum potassium values are in marked contrast to those observed when the serum potassium value is abnormally high. Thus, in patients with a low value, low-voltage QRS complexes and lowering or actual inversion of the T waves are observed. The ST segments may become depressed, and the QRS interval may be prolonged. In contrast, the electrocardiogram in patients with a high level may show an absence of the P waves, wide QRS complexes and high, peaked T waves.

SERUM POTASSIUM LEVELS IN DIABETIC COMA*

RICHARD H SINDEN, M D,† JAMES L TULLIS, M D,‡ AND HOWARD F ROOT, M D§

BOSTON

THE clinical importance of variations in the serum potassium level during treatment of diabetic coma has been emphasized by the reports of Holler,¹ Martin and Wertman,² Nicholson and Branning,³ Frenkel, Groen and Willebrands⁴ and Nadler, Bellet and Lanning.⁵ They reported low potassium values in certain patients undergoing treatment for diabetic coma, with fatal results unless suitable potassium solutions were administered promptly. On the other hand, studies of serum potassium levels in conditions of shock, cardiac or renal failure indicate that if potassium is given as a therapeutic measure to patients with impending or actual renal failure, a dangerously high level of potassium in the blood serum may also have a fatal result. Today, the physician responsible for the treatment of patients in diabetic coma, must

coma, such a loss may be very severe. This is especially true in previously undiagnosed cases.

It is the purpose of this paper to present 6 cases of diabetic coma in which routine potassium observations were made. All cases were studied in the George F Baker Clinic of the New England Deaconess Hospital, and are reported to show the effect of treatment without glucose on varying degrees of acidosis.

CASE REPORTS

CASE 1 This patient, a child, was not known to have diabetes until she was found in a drowsy state after several days of nausea and vomiting. On admission to the hospital the blood sugar was 400 mg per 100 cc, and the serum potassium was 3.1 milliequiv per liter. At the end of 17 hours of treatment the serum potassium fell to 2.5 milliequiv, but she had no referable symptoms and made an uncomplicated recovery with only 66 units of insulin and 1000 cc of physiologic saline solution intravenously (Table 1).

TABLE 1 Serum Potassium Levels in Diabetic Acidosis

have constantly in mind the possibility that critical alterations in the level of blood serum potassium may result in a fatal outcome unless proper treatment is given in an early stage.

The causes of a decline in the serum level of potassium from a normal of around 5.0 milliequiv per liter to levels of 3.0 milliequiv or less are varied. It has long been known that during acidosis, particularly of the diabetic type, there is an immediate and increasing loss of potassium in the urine. This potassium comes chiefly from the cells through disturbance in cellular permeability occurring during diabetic coma. A considerable loss of potassium in the urine may occur before extracellular levels are seriously affected. In cases of diabetic

CASE 2 A 19-year-old girl in diabetic acidosis for the second time had made very little attempt to control her diabetes. She had not followed the prescribed diet, nor had she checked her urine for sugar. Polyuria and polydipsia had been present for several weeks. Three days prior to admission abdominal pain had developed, followed in 48 hours by nausea and vomiting. After twenty-four hours of vomiting she was admitted to the hospital in a semiconscious state. The first hour's treatment consisted of intravenous administration of physiologic saline solution and 200 units of regular insulin. The admission potassium of 5.8 milliequiv per liter fell to 3.8 milliequiv in the next 24 hours. Recovery was uncomplicated.

CASE 3 This young woman followed very closely the pattern of Case 2, except that vomiting was present 48 hours prior to admission. The serum potassium levels were correspondingly lower, but her recovery was uneventful.

CASE 4 A middle-aged man had not been seen in the clinic for 2 years and had made very little effort to control his diabetes. In spite of the distressing symptoms of uncontrolled diabetes, he had continued eating a diet liberal in carbohydrate and maintained an inadequate insulin dosage. Nausea and vomiting began while he was on his way to the hospital from another state. After 4½ hours of vomiting he arrived at the hospital in fairly good condition with a blood sugar of 805 mg per 100 cc, and a carbon dioxide content

DELAYED PNEUMONIA AND URTICARIA FOLLOWING BRONCHOGRAPHY

H E BASS, M D *

NEW YORK CITY

PNEUMONIA complicating bronchography has been described¹⁻⁴ Some of the cases previously reported have been attributed to infectious factors, owing to the carrying down of infecting organisms from the upper respiratory tract Waldbott¹ has emphasized the role of iodized oil in producing obstruction of the small bronchi followed by atelectasis of lung tissue and pneumonitis or massive collapse of a lung when a main bronchus is involved Other authors have reported cases of pneumonia believed to be due to an allergic reaction to the iodide component of lipiodol² All the reported cases, whether infectious or allergic, were characterized by a rapid onset of pneumonia, which usually occurred within twenty-four or forty-eight hours

A number of fatal cases have also been reported In 1 of these cases death occurred about seventy-five minutes after instillation of the iodized oil⁴ On post-mortem examination, both lungs were atelectatic, and the tracheobronchial tree was completely filled with thick, extremely tenacious mucus, which was found plugging even the smallest bronchioles These deaths were considered to be allergic and were directly attributed to the iodine fraction of the iodized oil used

More recently, 3 cases of pneumonia following the use of lipiodol in asthmatic patients were described that differed from those previously reported⁵ A delayed onset of pneumonia was noted, varying between nine and twelve days In addition,

these cases were characterized by certain allergic manifestations such as urticaria, blood eosinophilia and positive sensitivity tests with iodide-containing compounds The delayed pneumonic reaction was described as resembling the delayed reaction of serum sickness In view of the increasing use of lipiodol as a diagnostic procedure in the field of thoracic disease, one may expect to see more cases of this type of complication following bronchography

CASE REPORT

W P, a 59-year-old man, was admitted to the Municipal Sanatorium on July 17, 1947 There was no familial history of tuberculosis He stated that in November, 1940, he had suffered an attack of "pleurisy and pneumonia" for which he had been treated at home A chest x-ray film taken in 1941 was reported as normal He subsequently became an employee of the Municipal Sanatorium, where a chest x-ray examination in June, 1946, showed a healed primary complex, with calcifications at both hilar areas In July, 1947, a nonproductive cough developed, and a chest film revealed an area of infiltration in the left lung He was admitted to the Sanatorium as a suspected case of pulmonary tuberculosis

Physical examination was within normal limits except for a soft blowing systolic murmur transmitted to the left. The lungs were clear The blood pressure was 160/90 The sedimentation rate was 8 mm per hour (Westergren method) A Mazzini test was negative The urine showed no abnormal findings During the period of hospital observation, ten concentrated sputum smears and four gastric cultures were negative for tubercle bacilli X-ray examination of the chest revealed a mottled infiltration in the left-upper-lung field containing a central, oval-shaped area of homogeneous opacity This infiltration showed some increase in its extent shortly after admission, but subsequently regressed

Bronchoscopic examination performed on April 12, 1948, was negative, however, the left-upper-lobe bronchus could not be visualized It was believed that a bronchogram should be taken because of the possibility of an underlying bronchiectatic condition Accordingly, a bronchogram was taken

*Clinical instructor in medicine New York Medical College associate visiting physician Municipal Sanatorium Otisville New York

A serum potassium value exceeding 12 milliequiv per liter may be and has been reported as fatal Paralysis may be flaccid or of the spastic type A more detailed discussion of electrocardiographic changes in various conditions is beyond the scope of this paper The subject is adequately covered by Milhorat⁸ and by Brown, Currens and Marchand⁹ and others^{5, 10, 11}

Currens and White¹² noted a fall in the serum potassium levels during treatment of patients with Addison's disease by means of desoxycorticosterone acetate They believed that the weakness associated with this treatment was often due to potassium loss The changes in the electrocardiogram accompanying high values of serum potassium are discussed by Tarail¹³ in a case of uremia and have also been described by Thorn,¹⁴ who cites the article on the clinical syndrome of potassium intoxication by Finch, Sawyer and Flynn¹⁵

Treatment of low serum potassium has proved successful in the cases of Holler,¹ Nicholson² and Frenkel,⁴ who use potassium chloride orally or begin with 100 cc of a 2 per cent solution intravenously Because glucose requires phosphorylation before it can be utilized, it seems wise to employ a combination of potassium and phosphate in cases that require intravenous administration of potassium salts In all such cases, however, the injection should be given slowly to avoid a transitory rise in the serum level to a dangerous concentration, and the diagnosis should be established with certainty either by means of actual serum analysis or unequivocal symptomatology and electrocardiographic findings For high serum potassium values, treatment of the underlying cause of renal insufficiency is indicated

The prevention of low serum potassium levels is possible by early and more rapid treatment of diabetic acidosis Every effort should be made to shorten the period of serious diabetic acidosis This means prompt use of insulin, when possible, long before the patient becomes drowsy Since, thus far, no patient has developed serious clinical hypokalemia unless intravenous glucose solution was administered during the first six to eight hours of treatment, one of the fundamental principles is to give no glucose in the first hours of treatment in diabetic acidosis

The excessive administration of glucose, especially with insulin, results in a rapid deposition of glycogen in the liver, associated with an intracellular shift of potassium, as shown by the experimental work of Fenn^{16, 17} Weissberg's¹⁸ patient received glucose intravenously and subsequently developed a serum potassium level of 1 milliequiv per liter—the lowest level recorded in the literature In the case reported by Tuynman and Wilhelm¹⁹ a low serum potassium level with respiratory difficulty developed after the patient had received glucose from the onset of treatment of diabetic coma They cite the work of Allott and

McArdle²⁰ in which 3 cases of periodic familial paralysis showed that attacks of paralysis, clinically identical with a naturally occurring attack, could be produced by the administration of glucose by mouth and by insulin but more consistently by glucose and insulin together

At the New England Deaconess Hospital during the three years ending April 1, 1948, 91 consecutive cases of diabetic coma have been treated without glucose and without a single death in spite of such complications as pneumonia, cerebrovascular accidents, heart disease, coronary occlusion and chronic nephritis The mere storage of excess glycogen has no value during the first few hours of the emergency in diabetic coma If 200 gm of glucose is given in the first few hours of treatment of diabetic acidosis, no more than 10 gm of glucose can be oxidized each hour²¹ The remainder must be excreted in the urine, deposited as glycogen (thereby producing a further reduction of serum potassium) or converted into fatty acids, as shown clearly by the isotopic studies of Stetten²²

Diabetic coma should always be considered an emergency in which the main object is to give an adequate amount of insulin in the first hours, to restore fluid balance promptly and to guard against potassium abnormalities In most cases, it is possible to start giving food orally after six to twelve hours It is the practice of this clinic to use food, such as oatmeal gruel and orange juice, which contain potassium, as soon as the stomach will retain it It is therefore timely and important in all cases of coma to wash out the dilated stomach and give an enema, to prepare the stomach for the taking of food at as early a period as possible Naturally, in patients remaining unconscious for twenty-four to forty-eight hours this procedure cannot be carried out, and intravenous feedings utilizing glucose become necessary In these cases the danger that hypokalemia will develop must be kept constantly in mind The prevention of fatal potassium intoxication may depend chiefly upon the avoidance of errors and the omission of potassium without definite indications

SUMMARY

Six cases of low potassium levels in diabetes from the George F Baker Clinic of the New England Deaconess Hospital are reported and discussed

Emergency serum potassium levels may occur during the treatment of diabetic coma and must constantly be kept in mind

The cause, diagnosis, treatment and prevention of high and low serum potassium levels are compared

For the prevention of dangerously low serum potassium values in diabetic coma, the omission of glucose administration during the first hours of treatment and more aggressive use of insulin are recommended

cases of lipiodol pneumonia originally reported⁵ sulfathiazole was employed but later discarded since no evident shortening of the period of illness was observed. It is possible that antihistaminic drugs exert a favorable influence on this type of pulmonary infiltration, and it is suggested that this form of therapy be employed.

A history of either familial or personal allergy is usually obtained in these cases. In such an event, iodine-sensitivity tests should be performed. The intracutaneous test with diodrast is perhaps as valuable as any.⁹ However, a negative skin test prior to bronchography is no safeguard against the development of a delayed lipiodol reaction.

In the case reported above, it should be noted that iodine-sensitivity tests were negative about two weeks after the disappearance of the urticarial eruption. Peck and his co-workers¹⁰ have described a similar finding in cases of urticarial reaction due to penicillin. They believe that although a positive reaction to a penicillin test is helpful in confirming a diagnosis of this type of allergy, a negative reaction does not exclude it. Since the reaction to penicillin may be positive in more than a third of such persons, the test is considered worth doing in an effort to prove that an eruption is due to penicillin. Furthermore, it has been pointed out by Lyons¹¹ that the induced urticarial form of penicillin allergy is often temporary, even transient. This observation has been borne out by Peck et al., who describe 2 patients whose initial reactions to the cutaneous test were positive, but in whom retests gave negative results. They imply that the mechanism by which the urticarial eruption is terminated is related to the reduction in sensitivity that may follow a violent reaction. It is possible that the status of the iodine-sensitivity test in cases of delayed lipiodol reactions is analogous to that obtaining in cases of delayed penicillin reactions.

In view of the foregoing observations, it is evident that an effort should be made to keep patients under observation for at least two weeks after bronchography. This is not always the case with clinic patients, who are frequently discharged after negative bronchographic tests. Iodine-sensitivity tests should be performed in patients who give a familial or personal history of allergy. In the presence of a positive test, bronchography might still be performed if the information to be gained therefrom is considered necessary for the carrying out of a surgical procedure such as pulmonary resection for localized bronchiectasis. In such cases an effort should be made to avoid overfilling of the bronchial tree. Trapping of lipiodol in the alveoli by explosive coughing should also be avoided. This can be accomplished by emptying of the bronchi, with postural drainage after completion of the examination. In addition, the use of antihistaminic drugs as a prophylactic measure against allergic reactions

for at least two weeks after bronchography is worthy of consideration.

SUMMARY

A case of delayed pneumonia and urticaria following bronchography in an allergic person is described.

The mechanism of delayed reactions to iodized oil is discussed.

on the left side on July 31 (Fig. 1). About 8 cc. of lipiodol was instilled into both lobes of the left lung by means of an intratracheal catheter. No immediate untoward reaction was noted. The bronchogram showed suggestive bronchiectatic changes in the left-upper-lung field.

Fourteen days later the patient first noted the onset of productive cough. The temperature, which had been normal, rose to 100.4°F. At the same time, an extensive itching skin

that is characterized by a definite incubation period of one to three weeks may occur, the familiar phenomenon of serum sickness belongs in this category. Urticarial reaction of a serum-sickness type occurring after a definite incubation period is a well known complication of penicillin therapy. As described by Kolodny and Denhoff,⁷ this reaction is a delayed type because of the time needed for development of the newly induced sensitivity.

A similar time lag occurs in the type of pulmonary reaction to lipiodol in the case described above. The interval before symptoms appear may be from seven to fourteen days and even longer. The symptoms may be acute and may resemble the onset of a bacterial or virus pneumonia. Urticaria is frequently seen. Severe rashes of urticarial type occurring seven to ten days after injection of iodized oil have been described by Scadding.⁸ Cough, expectoration of a mucoid spu-

Note the suggestive bronchiectatic changes in the left-upper-lung field.

eruption which was urticarial and covered the arms, legs and trunk developed. On questioning, the patient stated that he had had a similar eruption, which he described as "hives," on several previous occasions.

A chest x-ray film taken on August 18 (Fig. 2) showed an extensive area of pneumonia occupying the lower-left-lung field. Numerous small densities representing retained lipiodol were visible throughout the left lung. Rales were heard at the left base for the first time. In spite of the rather extensive area of pneumonia visible on x-ray study, the patient appeared surprisingly comfortable. The temperature fell by lysis and reached normal levels after 5 days. A chest x-ray film taken on September 3 (Fig. 3) showed some regression of the area of pneumonic density, which still occupied the base of the lung. No allergic studies were performed at the time of the acute illness. However, a blood count done 2 weeks after the disappearance of the urticarial eruption did not reveal any increase in eosinophilic leukocytes. Iodine-sensitivity tests were also carried out at this time. An oral test with potassium iodide, a scratch test with lipiodol and an intracutaneous test with diodrast were negative.

DISCUSSION

Immediate allergic reactions to iodine in hypersensitive persons have been described.⁶ These reactions are analogous to those produced by serum therapy in patients sensitive to horse serum. In nonsensitized subjects a form of induced sensitivity

FIGURE 2 Film Taken on August 19, 1948, Showing Extensive Area of Confluent Pneumonia at the Left Base. There are numerous small area densities representing retained lipiodol in the remainder of the left lung.

tum and fever are prominent symptoms. The temperature is often low grade, whereas the extent of pulmonary involvement may be quite massive. Rales are heard over the involved portion of the lung field, usually at the base. Roentgenographic examination often reveals a confluent type of pneumonic density conforming to the area of distribution of lipiodol. Treatment is symptomatic. In the

cases of lipiodol pneumonia originally reported⁵ sulfathiazole was employed but later discarded since no evident shortening of the period of illness was observed. It is possible that antihistaminic drugs exert a favorable influence on this type of pulmonary infiltration, and it is suggested that this form of therapy be employed.

A history of either familial or personal allergy is usually obtained in these cases. In such an event, iodine-sensitivity tests should be performed. The intracutaneous test with diodrast is perhaps as valuable as any.⁹ However, a negative skin test prior to bronchography is no safeguard against the development of a delayed lipiodol reaction.

In the case reported above, it should be noted that iodine-sensitivity tests were negative about two weeks after the disappearance of the urticarial eruption. Peck and his co-workers¹⁰ have described a similar finding in cases of urticarial reaction due to penicillin. They believe that although a positive reaction to a penicillin test is helpful in confirming a diagnosis of this type of allergy, a negative reaction does not exclude it. Since the reaction to penicillin may be positive in more than a third of such persons, the test is considered worth doing in an effort to prove that an eruption is due to penicillin. Furthermore, it has been pointed out by Lyons¹¹ that the induced urticarial form of penicillin allergy is often temporary, even transient. This observation has been borne out by Peck et al., who describe 2 patients whose initial reactions to the cutaneous test were positive, but in whom retests gave negative results. They imply that the mechanism by which the urticarial eruption is terminated is related to the reduction in sensitivity that may follow a violent reaction. It is possible that the status of the iodine-sensitivity test in cases of delayed lipiodol reactions is analogous to that obtaining in cases of delayed penicillin reactions.

In view of the foregoing observations, it is evident that an effort should be made to keep patients under observation for at least two weeks after bronchography. This is not always the case with clinic patients, who are frequently discharged after negative bronchographic tests. Iodine-sensitivity tests should be performed in patients who give a familial or personal history of allergy. In the presence of a positive test, bronchography might still be performed if the information to be gained therefrom is considered necessary for the carrying out of a surgical procedure such as pulmonary resection for localized bronchiectasis. In such cases an effort should be made to avoid overfilling of the bronchial tree. Trapping of lipiodol in the alveoli by explosive coughing should also be avoided. This can be accomplished by emptying of the bronchi, with postural drainage after completion of the examination. In addition, the use of antihistaminic drugs as a prophylactic measure against allergic reactions

for at least two weeks after bronchography is worthy of consideration.

MEDICAL PROGRESS

INDUSTRIAL MEDICINE

IRVING R. TABERSHAW, M.D.*

NEW YORK CITY

DURING the past year emphasis was placed on the social phases of industrial medicine. With the responsibility for control of the physical environment falling more and more to the technical specialists in industry, the factors involved in the worker's mental and social welfare were of growing concern to industrial physicians. Throughout the field greater co-ordination among all those involved, and more research and educational activities, were seen essential. As industrial medicine reaches full stature, the further necessity for it to assume a well defined place in the complex social scheme, consistent with the interests of the entire medical profession, becomes apparent. What is to be its scope — its limitations? The question is still unanswered.

The industrial physician today may be said to be at the crossroads.¹ Without deviating from the basic tenets of the profession, he has been compelled to adapt himself to the demands of a fast-developing and changing industrial economy. Each of the various forms of health insurance, group-term life insurance, accident and sickness insurance, pension funds and sick-benefit and pension plans has assumed a more significant part in relation to occupational medicine. The very nature of the industrial practitioner's work, dealing as it does with a specified segment of society, has placed him in an anomalous position. For example, although he adheres in theory to the established precept of the patient's free choice of a doctor, he cannot but violate it in actual practice.

Only further exploration of the situation — from the standpoints of industry, the medical profession and the community in general — can determine how far and how fast industrial medicine will travel. "The ultimate possibilities may be considered as narrowly or as broadly as vision and faith will permit."²

The continuing introduction of new manufacturing materials and processes brought scientific advances over a wide front, but no startling discoveries were announced. Many of the investigations into potential health hazards in various industries were incomplete. However, such important developments as were noted are reviewed below.

BERYLLIUM AND ATOMIC RADIATION

The epidemiology of beryllium poisoning is not completely understood, but the various clinical

manifestations produced by this metal have been more clearly defined and definite progress has been made toward its control.³⁻⁵ There is no longer any controversy about its toxicity since a significant health hazard can be shown to exist wherever beryllium dust or fume contaminates the atmosphere.

The contact dermatitis that appears in from three to ten days in workers processing beryl ore is of relatively minor consequence, but may be a precursor to the development of the acute or chronic form in susceptible persons. Approximately 50 per cent of workers will develop skin manifestations from contact with beryllium compounds that contain an acid radical, notably beryllium sulfate or beryllium fluoride.⁶ Ulceration may occur if a crystal of a soluble beryllium salt is introduced into the skin. These ulcerations do not heal readily until the base is curetted. Granulomatous skin lesions similar to sarcoid occur occasionally in people with the chronic form of pulmonary disease and are considered part of the generalized process. Grier et al.⁷ and Shook and Powell⁸ have recently described subcutaneous granulomas at the site of lacerations in people who have suffered cuts from fluorescent lamps coated with a zinc manganese beryllium silicate. The pathology of these granulomas is similar to that found in the lungs in cases of chronic pulmonary granulomatosis. Treatment by complete excision is effective. Disposal of burned-out fluorescent tubes is a hazard. Such tubes should be broken under water or disposed of intact, so as to prevent liberation of dust and possible implantation under the skin.

Exposure to soluble salts may produce chemical inflammatory changes in the respiratory tract and conjunctiva. Nasopharyngitis and tracheobronchitis are usually of transient nature and clear up upon removal from exposure. Acute pneumonitis is more serious and not infrequently fatal. The incidence and severity are related to the degree of exposure, the nature of the beryllium compound, particle size, surface area and so forth and to individual factors of susceptibility. The characteristic symptoms are dyspnea, cough, chest pain and cyanosis. Pulmonary infiltration undistinguishable by x-ray examination from generalized bronchopneumonia develops within a period of one to three weeks. Recovery, or death in the fulminating type, occurs within days to several months. At autopsy

*Assistant professor of industrial hygiene, Columbia University School of Public Health, medical director, Eastern Division, Liberty Mutual Insurance Company, New York.

the lungs show a diffuse bronchopneumonitis similar to that in any chemical pneumonitis. The liver and spleen are enlarged and show changes consistent with an overwhelming chemical toxemia. The treatment is supportive and consists chiefly of oxygen, bed rest, antihistaminics and penicillin as a prophylactic.

These acute cases have occurred among workers engaged in the refining of beryl ore, in the manufacture of fluorescent lamps, in ceramics and in the machining of the pure metal. The use of beryllium copper products is not harmful, but when these alloys are ground, melted or tooled, contamination of the atmosphere with dust or fume may occur and produce some form of the disease. The highest incidence of acute pneumonitis is found in exposure to beryllium sulfate or fluoride, and cases have been known to develop after a single twenty-minute exposure to high concentrations.⁹ Maximum allowable concentrations have not been agreed upon but are judged to be in the range of 25 microgm per cubic meter for the acute disease. Engineering revisions of the industrial processes have reduced the incidence of acute pneumonitis to a very low level. Medical control by weekly examination, with particular emphasis on the vital capacity, which is diminished early, and prophylactic lav-off often lessen the severity and limit the tracheobronchial form from progressing.

The chronic form of the disease is characterized by a long delay between exposure and the onset of symptoms. Anywhere from four months to six years after the cessation of exposure, shortness of breath and loss of weight may develop. These symptoms continue until the patient dies, although some seem to have made a partial recovery. Pascucci,¹⁰ in a comprehensive review of the roentgen findings describes two types: a bilateral, uniformly widespread, diffuse granulomatous lesion and nodular infiltration. This fine, disseminated, granular type of infiltration is characteristic and not produced by any other definite pathologic entity. Pulmonary changes visible on x-ray study may exist without significant or any symptomatology. No clear-cut correlation can be drawn between the clinical features of the disease and the roentgenologic appearance of the lesions. Autopsy in the chronic cases shows a diffuse, nodular, granular, inflammatory response characterized by giant cells, epithelioid cells, plasma cells and inclusion bodies and by fibrosis. Pulmonary hypertension from reduction in the size of the pulmonary vascular bed is the most common cause of death. Other viscera, such as the hilar lymph nodes and the liver and spleen, show granulomatous infiltration and extensive fibrosis similar to that in the lung.

The vast majority of patients with a chronic disease give no history of an acute episode. Cases of the chronic disease have also occurred in people who were never exposed within an industrial plant

but lived in close proximity to a factory using a beryllium compound, as well as in the families of workers, the exposure apparently produced indirectly by contamination with work clothes. Follow-up examination on a number of workers with the acute disease indicates that most of them have recovered completely. But there are several cases that after a delay of months to years developed the typical clinical picture of the chronic disease. The presence, however, of such cases and the known long delay in onset leaves the question of progress from acute to chronic still undecided.¹¹

The prevention of the chronic case is difficult, but periodic examinations of exposed people, including x-ray films of the chest and vital-capacity determinations, are necessary for early diagnosis. Plant sanitation, as well as obligatory washing, showers and change of clothing, is essential for control. Substitution or segregation of beryllium processes will limit the incidence of the chronic disease.

Significant progress has been made in the determination of beryllium in air and body tissues.¹² Analyses of normal tissue indicate that the amount of beryllium is less than 0.05 microgm per 100 gm of wet-lung tissue and that normal urine contains no beryllium. Acute cases may show as much as 180 microgm per 100 gm of lung. The urine of exposed workers who show no symptoms may contain as much as 1.2 microgm of beryllium per liter, whereas those suffering from acute pneumonitis may show as much as 4.2 microgm of beryllium per liter of urine. The urine of patients with chronic granulomatosis varies from negative to 1.4 microgm of beryllium per liter. Lung tissue in chronic cases contains between 0.05 and 1.6 microgm. The variability and the technical difficulties of doing the beryllium determination in tissue indicate that reliance should not be placed on beryllium tissue content as pathognomonic of the disease, but rather as evidence of exposure to beryllium.

Industrial development of atomic energy has not progressed to the point where it is of significance to most industrial physicians. Results of experiments, however, by workers associated with the atomic program have appeared in quantity in the literature. Of particular interest to the industrial physician is the evidence that hematologic studies for the reduction of lymphocytes in the peripheral blood are still the most sensitive indicator of exposure to ionizing radiation.¹³ More caution in exposure to radiation is beginning to be prevalent among health physicists, who suggest that the tolerance dose be decreased from 0.1 r to 0.05 r per day, or a maximum of 0.3 r per week.¹

PNEUMOCOINOSIS

Although a large number of articles were published describing the occurrence, distribution and characteristics of silicosis in various dusty indus-

DURING the past year emphasis was placed on the social phases of industrial medicine. With the responsibility for control of the physical environment falling more and more to the technical specialists in industry, the factors involved in the worker's mental and social welfare were of growing concern to industrial physicians. Throughout the field greater co-ordination among all those involved, and more research and educational activities, were seen essential. As industrial medicine reaches full stature, the further necessity for it to assume a well defined place in the complex social scheme, consistent with the interests of the entire medical profession, becomes apparent. What is to be its scope — its limitations? The question is still unanswered.

The industrial physician today may be said to be at the crossroads.¹ Without deviating from the basic tenets of the profession, he has been compelled to adapt himself to the demands of a fast-developing and changing industrial economy. Each year the various forms of health insurance, group-welfare funds and sick-benefit and pension plans play a more significant part in relation to occupational medicine. The very nature of the industrial practitioner's work, dealing as it does with a specified segment of society, has placed him in an anomalous position. For example, although he adheres in theory to the established precept of the patient's free choice of a doctor, he cannot but violate it in actual practice.

Only further exploration of the situation — from the standpoints of industry, the medical profession and the community in general — can determine how far and how fast industrial medicine will travel. "The ultimate possibilities may be considered as narrowly or as broadly as vision and faith will permit."²

The continuing introduction of new manufacturing materials and processes brought scientific advances over a wide front, but no startling discoveries were announced. Many of the investigations into potential health hazards in various industries were incomplete. However, such important developments as were noted are reviewed below.

BERYLLIUM AND ATOMIC RADIATION

The epidemiology of beryllium poisoning is not completely understood, but the various clinical

manifestations produced by this metal have been more clearly defined and definite progress has been made toward its control.³⁻⁵ There is no longer any controversy about its toxicity since a significant health hazard can be shown to exist wherever beryllium dust or fume contaminates the atmosphere.

The contact dermatitis that appears in from three to ten days in workers processing beryl ore is of relatively minor consequence, but may be a precursor to the development of the acute or chronic form in susceptible persons. Approximately 50 per cent of workers will develop skin manifestations from contact with beryllium compounds that contain an acid radical, notably beryllium sulfate or beryllium fluoride.⁶ Ulceration may occur if a crystal of a soluble beryllium salt is introduced into the skin. These ulcerations do not heal readily until the base is curetted. Granulomatous skin lesions similar to sarcoid occur occasionally in people with the chronic form of pulmonary disease and are considered part of the generalized process. Grier et al.⁷ and Shook and Powell⁸ have recently described subcutaneous granulomas at the site of lacerations in people who have suffered cuts from fluorescent lamps coated with a zinc manganese beryllium silicate. The pathology of these granulomas is similar to that found in the lungs in cases of chronic pulmonary granulomatosis. Treatment by complete excision is effective. Disposal of burned-out fluorescent tubes is a hazard. Such tubes should be broken under water or disposed of intact, so as to prevent liberation of dust and possible implantation under the skin.

Exposure to soluble salts may produce chemical inflammatory changes in the respiratory tract and conjunctiva. Nasopharyngitis and tracheobronchitis are usually of transient nature and clear up upon removal from exposure. Acute pneumonitis is more serious and not infrequently fatal. The incidence and severity are related to the degree of exposure, the nature of the beryllium compound, particle size, surface area and so forth and to individual factors of susceptibility. The characteristic symptoms are dyspnea, cough, chest pain and cyanosis. Pulmonary infiltration undistinguishable by x-ray examination from generalized bronchopneumonia develops within a period of one to three weeks. Recovery, or death in the fulminating type, occurs within days to several months. At autopsy

should be reduced from 75 to 35 parts per million, and Forssmann and Frickholm¹⁰ state that exposure to benzene creates an increased demand for vitamin C and that an extra supply increases the resistance to the effects of this toxin. Clinton¹¹ describes an accident in which a large amount of selenium was released in the air. No systemic toxic effects were noted, and only severe local irritation occurred. A comprehensive review of the acute effects and treatment of chlorine inhalation was described by Chasis et al.¹² when over 400 people were accidentally poisoned with this gas after rupture of a chlorine tank. No chronic pulmonary sequelae were noted in any of the patients who were followed for sixteen months although some had persistent anxiety reactions.

DERMATITIS

With occupational dermatitis constituting approximately 65 per cent of all cases of occupational diseases,¹³⁻¹⁴ the dermatologic problem continued to demand constant vigilance and study on the part of the industrial physician. No outstanding developments were reported in this field, but over-all methods of control were reviewed by a number of authorities. All were agreed on the importance of preventive measures such as provision of proper cleansing facilities, substitution of nonirritating materials when possible, use of protective clothing and creams, and careful placement of employees.

Criteria for determining the industrial status of skin diseases were discussed by Bulmer,¹⁵ Macauley,¹⁴ Downing¹⁶ and others. About 40 per cent of a large number of cases of employees claiming compensation for occupational dermatitis, on which Downing reported, were proved to be of nonindustrial origin. Approximately 20 per cent or less of industrial skin diseases are allergic, according to Tolmach,¹⁶ but the percentage was difficult to determine since diagnoses were frequently based on inaccurate histories or solely on patch tests, improperly applied.

The skin hazards in 114 occupations and the newer therapeutic agents, as well as dermatoses due to wearing apparel and to various cosmetic preparations, were considered by Schwartz et al.¹⁷ In the last-named category, a cause of dermatitis, mentioned elsewhere,¹⁸ is prolonged or frequent contact with the so-called "cold" permanent hair-waving preparations. Employees' exposures to skin hazards away from work, as well as on the job, should be taken into account before the physician renders his final opinion about the etiologic agent in each case.¹⁹ Investigations were reported on different occupations, such as flour allergy with cutaneous reactions,²⁰ paint-factory workers and painters with occupational dermatoses,²¹ workers exposed to pitch, tar or tar products²²⁻²³ and farmers and others suffering from grain itch.²⁴⁻²⁵ Other occupations studied for their skin hazards were those of long-

shoremen²⁶ and workers in the jewelry industry²⁷ and in the poultry industry.²⁸

Numerous procedures for the control of specified occupational skin hazards were recommended. For employees working with chromium salts, the use of a nasal paste of 5 per cent bismuth subnitrate in soft paraffin was found effective to prevent perforation. This method was adopted in German chromium plants, where 30 to 40 cases of lung cancer had occurred.²⁹ Reviewing the poisonous properties of DDT, Van Huut³⁰ advised the wearing of synthetic-rubber gloves and provision of good ventilation where it is being used. Solvents as vehicles for DDT were studied and reported on from the standpoint of their photosensitizing action on the skin.³¹ Carbitol, which is being used more and more in cosmetic or other preparations for the skin, can constitute a health hazard, if uncontrolled.³² Temporary loss of hair among workers in neoprene-manufacturing plants occurs only in the polymerization areas, it was found.³³ No satisfactory treatment or protective headgear was developed, but the condition was controlled or eliminated by frequent and complete changes of air in the polymerization areas. In general, precautions should be taken not only in the particular location where any irritant fume or solvent mist is present but also in nearby areas to which air currents can transport such agents, according to Campbell,³⁴ who observed several cases of dermatitis due to this indirect type of exposure.

The testing of a large number of protective-glove materials for their permeability to tetraethyl lead and ethylene bromide led Calingaert and Shapiro³⁵ to conclude that nylon and also nylon compounded with neoprene are the most impermeable and best suited for this purpose. Various barrier creams were investigated by Cumming³⁶ and others, with a view to lowering the high incidence of dermatitis in industries manufacturing explosives, particularly tetryl and other nitrocompounds. A new protective cream, with liquid paraffin forming the basis, was developed. Other barrier creams, for workers handling the soluble phenols and cresol formaldehyde products, and for workers exposed to pitch, were reported by Weldon.³⁷

REHABILITATION AND JOB PLACEMENT

The proposition that rehabilitation of the disabled worker is a vital function of industrial medicine is being accepted more and more widely, here and abroad. The need for veterans' rehabilitation programs had been recognized and acted upon early in the post-war period, but until more recently such programs were only very rarely extended to include the physically impaired among civilian industrial workers. That a large potential of human productivity was being by-passed by industry — to the detriment of industry itself, as well as of the community at large — was frequently noted. To overcome the resistance of industry in accepting phys-

tries, no significant revisions were suggested in the diagnosis, epidemiology, management or control of the disease. It is interesting in this connection to note the finding of McCormick et al.¹⁵ that in the processing of leaf tobacco the inhalation of hygienically significant free silica in the tobacco dust may present a hazard.

Exposure factors were more carefully studied in several articles, with special reference to particle-size distribution. Hatch and Kindsvatter¹⁶ indicate that particles below 0.5 microns may be of greater import than was previously thought. The importance of quantitative evaluation of the influence of particle size upon toxic activity of dust is stressed,¹⁷ and Holden and his associates¹⁸ state that the free silica content of the fraction below 5 microns provides a more significant measure of the silicosis dust potentiality than the total dust analysis.

More cases of bagassosis, a pulmonary disease resulting from the inhalation of bagasse dust, were reported.¹⁹ Bagasse, a sugar-cane waste product, is used in the manufacture of insulating and acoustic board, and its dust produces sudden cough, severe dyspnea, chills and fever and occasional hemoptysis. X-ray study discloses diffuse mottling of both lungs, which clears in from two weeks to several months. Numerous etiologies have been suggested,²⁰ but the most recent work of Schneider et al.²¹ indicates that the cause of the disease is *Aerobacter cloacae* (a soil bacterium also present in cotton) acting in conjunction with the inhaled particles of the irritant bagasse dust.

Aluminum and some of its oxides have been shown experimentally to inhibit the action of silica in producing silicosis, and extensive prophylactic and therapeutic clinical trials are presently under way. A new apparatus for dispensing the aluminum hydroxide dust is described by Church and Ingram.²² Riddell²³ cautions, however, against the acceptance that the treatment is of value since no conclusive objective evidence has as yet been brought out. The effect of aluminum inhalation in human beings is apparently chiefly psychologic in its effect. Although most of the evidence indicates that alumina is harmless, the finding of pulmonary fibrosis and pneumothorax in workers exposed to bauxite in the manufacture of corundum has been reported.²⁴ The fume generated in this process consists of finely divided silica and amorphous alumina. Similar experiences from Germany and Sweden²⁵ corroborate that some processes involving the manufacture of aluminum compounds produce a form of pneumoconiosis. A field study on the effect of alumina and silica is provided in the pottery industry, in which workers are exposed to finely powdered alumina and flint.²⁶ This group of workmen, although daily exposed to finely powdered alumina in greater intensity and over a longer period than existing methods of treatment could cope with, showed not only new cases of silicosis but also known

cases of the advanced form. Baetjer,²⁷ in a study of the effect of Portland-cement dust reported no effect on animal resistance to lobar pneumonia, differing in this respect from the effects of quartz and feldspar dust.

SPECIFIC CHEMICALS

The toxicologic properties of a host of new industrial chemicals were reported during the past year. Revisions of certain phases of knowledge of some of the older ones were also made. The absorption of lead through the skin was found to be very small for nonvolatile compounds such as lead oleate, lead acetate and lead arsenate. Volatile compounds, notably lead tetraethyl, penetrate the skin with great ease.²⁸ The maximum allowable concentration for lead, which has been standardized for some years at 1.5 mg per 10 cubic meters of air, has been criticized as not always applicable.²⁹ Insoluble lead compounds such as lead chromate are definitely less toxic, and review and standardization of each type of lead compound has been suggested. Experimental studies on the use of BAL, which had been found efficacious³⁰ in arsenic and mercury poisoning, showed that although it increases lead excretion, it apparently has no effect on decreasing the toxicity of the absorbable lead. Other lead antidotes, specifically a soluble dithizone, are being studied. A spectrophotometric method for rapid lead urinalysis shows great promise as a screening technic for lead absorption.³¹

Considerable attention was paid to the carcinogenic properties of various industrial chemicals. Evidence is accumulating rapidly that exposure to chromates greatly increases the incidence of pulmonary and other carcinomas.³² The number of cases of cancer in a factory handling arsenic indicates that there is an excess of deaths from this cause in such workers.³³ Carcinomas of the bladder from aniline do not occur because exposure is sufficiently well controlled, but beta-naphthylamine and benzidine still produce cases.^{34, 35}

Princi³⁶ doubts that cadmium, which is considered a severe industrial toxin, is capable of producing chronic effects. Friberg,³⁷ however, describes kidney damage in a group of workers exposed to nickel and cadmium, although previous reports in the literature give no direct evidence that either of these metals causes pathological changes in the kidney. An important contribution to the toxicity of sodium fluoride has been made by the Public Health Service³⁸ in a study of exposure at open-hearth furnaces. Irritating upper respiratory symptoms may occur, but there is no evidence of any pulmonary cardiovascular or skeletal findings of fluorosis. Also, no effect was noted on the teeth or tissues of the oral cavity in workers using sodium fluoride.

Hardy and Elkins³⁹ reached the conclusion that the maximum allowable concentration for benzene

should be reduced from 75 to 35 parts per million, and Forssmann and Frvholm¹⁰ state that exposure to benzene creates an increased demand for vitamin C and that an extra supply increases the resistance to the effects of this toxin. Clinton¹¹ describes an accident in which a large amount of selenium was released in the air. No systemic toxic effects were noted, and only severe local irritation occurred. A comprehensive review of the acute effects and treatment of chlorine inhalation was described by Chasis et al.¹² when over 400 people were accidentally poisoned with this gas after rupture of a chlorine tank. No chronic pulmonary sequelae were noted in any of the patients who were followed for sixteen months although some had persistent anxiety reactions.

DERMATITIS

With occupational dermatitis constituting approximately 65 per cent of all cases of occupational diseases,¹³⁻¹⁴ the dermatologic problem continued to demand constant vigilance and study on the part of the industrial physician. No outstanding developments were reported in this field, but over-all methods of control were reviewed by a number of authorities. All were agreed on the importance of preventive measures such as provision of proper cleansing facilities, substitution of nonirritating materials when possible, use of protective clothing and creams, and careful placement of employees.

Criteria for determining the industrial status of skin diseases were discussed by Bulmer,¹⁵ Macauley,¹⁴ Downing¹⁶ and others. About 40 per cent of a large number of cases of employees claiming compensation for occupational dermatitis, on which Downing reported, were proved to be of nonindustrial origin. Approximately 20 per cent or less of industrial skin diseases are allergic, according to Tolmach,¹⁶ but the percentage was difficult to determine since diagnoses were frequently based on inaccurate histories or solely on patch tests, improperly applied.

The skin hazards in 114 occupations and the newer therapeutic agents, as well as dermatoses due to wearing apparel and to various cosmetic preparations, were considered by Schwartz et al.¹⁷ In the last-named category, a cause of dermatitis, mentioned elsewhere,¹⁸ is prolonged or frequent contact with the so-called "cold" permanent hair-waving preparations. Employees' exposures to skin hazards away from work, as well as on the job, should be taken into account before the physician renders his final opinion about the etiologic agent in each case.¹⁹ Investigations were reported on different occupations, such as flour allergy with cutaneous reactions,²⁰ paint-factory workers and painters with occupational dermatoses,²¹ workers exposed to pitch, tar or tar products²²⁻²³ and farmers and others suffering from grain itch.²⁴⁻²⁵ Other occupations studied for their skin hazards were those of long-

shoremen²⁶ and workers in the jewelry industry²⁷ and in the poultry industry.²⁸

Numerous procedures for the control of specified occupational skin hazards were recommended. For employees working with chromium salts, the use of a nasal paste of 5 per cent bismuth subnitrate in soft paraffin was found effective to prevent perforation. This method was adopted in German chromium plants, where 30 to 40 cases of lung cancer had occurred.²⁹ Reviewing the poisonous properties of DDT, Van Huyt³⁰ advised the wearing of synthetic-rubber gloves and provision of good ventilation where it is being used. Solvents as vehicles for DDT were studied and reported on from the standpoint of their photosensitizing action on the skin.³¹ Carbitol, which is being used more and more in cosmetic or other preparations for the skin, can constitute a health hazard, if uncontrolled.³² Temporary loss of hair among workers in neoprene-manufacturing plants occurs only in the polymerization areas, it was found.³³ No satisfactory treatment or protective headgear was developed, but the condition was controlled or eliminated by frequent and complete changes of air in the polymerization areas. In general, precautions should be taken not only in the particular location where any irritant fume or solvent mist is present but also in nearby areas to which air currents can transport such agents, according to Campbell,³⁴ who observed several cases of dermatitis due to this indirect type of exposure.

The testing of a large number of protective-glove materials for their permeability to tetraethyl lead and ethylene bromide led Calingaent and Shapiro³⁵ to conclude that nylon and also nylon compounded with neoprene are the most impermeable and best suited for this purpose. Various barrier creams were investigated by Cumming³⁶ and others, with a view to lowering the high incidence of dermatitis in industries manufacturing explosives, particularly tetryl and other nitrobodyes. A new protective cream, with liquid paraffin forming the basis, was developed. Other barrier creams, for workers handling the soluble phenols and cresol formaldehyde products, and for workers exposed to pitch, were reported by Weldon.³⁷

REHABILITATION AND JOB PLACEMENT

The proposition that rehabilitation of the disabled worker is a vital function of industrial medicine is being accepted more and more widely, here and abroad. The need for veterans' rehabilitation programs had been recognized and acted upon early in the post-war period, but until more recently such programs were only very rarely extended to include the physically impaired among civilian industrial workers. That a large potential of human productivity was being by-passed by industry — to the detriment of industry itself, as well as of the community at large — was frequently noted. To overcome the resistance of industry in accepting phys-

tries, no significant revisions were suggested in the diagnosis, epidemiology, management or control of the disease. It is interesting in this connection to note the finding of McCormick et al.¹⁶ that in the processing of leaf tobacco the inhalation of hygienically significant free silica in the tobacco dust may present a hazard.

Exposure factors were more carefully studied in several articles, with special reference to particle-size distribution. Hatch and Kindsvatter¹⁸ indicate that particles below 0.5 microns may be of greater import than was previously thought. The importance of quantitative evaluation of the influence of particle size upon toxic activity of dust is stressed,¹⁷ and Holden and his associates¹⁸ state that the free silica content of the fraction below 5 microns provides a more significant measure of the silicosis dust potentiality than the total dust analysis.

More cases of bagassosis, a pulmonary disease resulting from the inhalation of bagasse dust, were reported.¹⁹ Bagasse, a sugar-cane waste product, is used in the manufacture of insulating and acoustic board, and its dust produces sudden cough, severe dyspnea, chills and fever and occasional hemoptysis. X-ray study discloses diffuse mottling of both lungs, which clears in from two weeks to several months. Numerous etiologies have been suggested,²⁰ but the most recent work of Schnitzer et al.²¹ indicates that the cause of the disease is *Aerobacter cloacae* (a soil bacterium also present in cotton) acting in conjunction with the inhaled particles of the irritant bagasse dust.

Aluminum and some of its oxides have been shown experimentally to inhibit the action of silica in producing silicosis, and extensive prophylactic and therapeutic clinical trials are presently under way. A new apparatus for dispensing the aluminum hydroxide dust is described by Church and Ingram.²² Riddell²³ cautions, however, against the acceptance that the treatment is of value since no conclusive objective evidence has as yet been brought out. The effect of aluminum inhalation in human beings is apparently chiefly psychologic in its effect. Although most of the evidence indicates that alumina is harmless, the finding of pulmonary fibrosis and pneumothorax in workers exposed to bauxite in the manufacture of corundum has been reported.²⁴ The fume generated in this process consists of finely divided silica and amorphous alumina. Also, no effect was noted on the teeth or tissues of the oral cavity in workers using sodium fluoride.

Hardy and Elkins³⁹ reached the conclusion that the maximum allowable concentration for benzene

should be reduced from 75 to 35 parts per million, and Forssmann and Frickholm⁴⁰ state that exposure to benzene creates an increased demand for vitamin C and that an extra supply increases the resistance to the effects of this toxin. Clinton⁴¹ describes an accident in which a large amount of selenium was released in the air. No systemic toxic effects were noted, and only severe local irritation occurred. A comprehensive review of the acute effects and treatment of chlorine inhalation was described by Chasis et al.⁴² when over 400 people were accidentally poisoned with this gas after rupture of a chlorine tank. No chronic pulmonary sequelae were noted in any of the patients who were followed for sixteen months although some had persistent anxiety reactions.

DERMATITIS

With occupational dermatitis constituting approximately 65 per cent of all cases of occupational diseases,⁴³⁻⁴⁴ the dermatologic problem continued to demand constant vigilance and study on the part of the industrial physician. No outstanding developments were reported in this field, but over-all methods of control were reviewed by a number of authorities. All were agreed on the importance of preventive measures such as provision of proper cleansing facilities, substitution of nonirritating materials when possible, use of protective clothing and creams, and careful placement of employees.

Criteria for determining the industrial status of skin diseases were discussed by Bulmer,⁴⁵ Macauley,⁴⁴ Downing⁴⁶ and others. About 40 per cent of a large number of cases of employees claiming compensation for occupational dermatitis, on which Downing reported, were proved to be of nonindustrial origin. Approximately 20 per cent or less of industrial skin diseases are allergic, according to Tolmach,⁴⁶ but the percentage was difficult to determine since diagnoses were frequently based on inaccurate histories or solely on patch tests, improperly applied.

The skin hazards in 114 occupations and the newer therapeutic agents, as well as dermatoses due to wearing apparel and to various cosmetic preparations, were considered by Schwartz et al.⁴⁷ In the last-named category, a cause of dermatitis, mentioned elsewhere,⁴⁸ is prolonged or frequent contact with the so-called "cold" permanent hair-waving preparations. Employees' exposures to skin hazards away from work, as well as on the job, should be taken into account before the physician renders his final opinion about the etiologic agent in each case.⁴⁹ Investigations were reported on different occupations, such as flour allergy with cutaneous reactions,⁵⁰ paint-factory workers and painters with occupational dermatoses,⁵¹ workers exposed to pitch, tar or tar products⁵²⁻⁵³ and farmers and others suffering from grain itch.⁵⁴⁻⁵⁵ Other occupations studied for their skin hazards were those of long-

shoremen⁵⁶ and workers in the jewelry industry⁵⁷ and in the poultry industry.⁵⁸

Numerous procedures for the control of specified occupational skin hazards were recommended. For employees working with chromium salts, the use of a nasal paste of 5 per cent bismuth subnitrate in soft paraffin was found effective to prevent perforation. This method was adopted in German chromium plants, where 30 to 40 cases of lung cancer had occurred.⁵⁹ Reviewing the poisonous properties of DDT, Van Huvt⁶⁰ advised the wearing of synthetic-rubber gloves and provision of good ventilation where it is being used. Solvents as vehicles for DDT were studied and reported on from the standpoint of their photosensitizing action on the skin.⁶¹ Carbitol, which is being used more and more in cosmetic or other preparations for the skin, can constitute a health hazard, if uncontrolled.⁶² Temporary loss of hair among workers in neoprene-manufacturing plants occurs only in the polymerization areas, it was found.⁶³ No satisfactory treatment or protective headgear was developed, but the condition was controlled or eliminated by frequent and complete changes of air in the polymerization areas. In general, precautions should be taken not only in the particular location where any irritant fume or solvent mist is present but also in nearby areas to which air currents can transport such agents, according to Campbell,⁶⁴ who observed several cases of dermatitis due to this indirect type of exposure.

The testing of a large number of protective-glove materials for their permeability to tetraethyl lead and ethylene bromide led Calingaert and Shapiro⁶⁵ to conclude that nylon and also nylon compounded with neoprene are the most impermeable and best suited for this purpose. Various barrier creams were investigated by Cumming⁶⁶ and others, with a view to lowering the high incidence of dermatitis in industries manufacturing explosives, particularly tetryl and other nitrocompounds. A new protective cream, with liquid paraffin forming the basis, was developed. Other barrier creams, for workers handling the soluble phenols and cresol formaldehyde products, and for workers exposed to pitch, were reported by Weldon.⁶⁷

REHABILITATION AND JOB PLACEMENT

The proposition that rehabilitation of the disabled worker is a vital function of industrial medicine is being accepted more and more widely, here and abroad. The need for veterans' rehabilitation programs had been recognized and acted upon early in the post-war period, but until more recently such programs were only very rarely extended to include the physically impaired among civilian industrial workers. That a large potential of human productivity was being by-passed by industry—to the detriment of industry itself, as well as of the community at large—was frequently noted. To overcome the resistance of industry in accepting phys-

ically impaired workers because of increased liabilities under the workmen's compensation laws, New York State amended its Second Injury Fund to provide equitable adjustment of the liability an employer assumes in the employment of a worker with any permanent physical impairment.⁶⁷

Hanman⁶⁸ observed that the physically handicapped comprise a majority of the population. He pointed further to the numerous studies that have shown that disabled employees, properly placed in industry, can be equal or superior to others. This estimation was proved correct in various reports on actual experience in the selective placement of the so-called unfit. The New Jersey Rehabilitation Commission⁶⁹ and the Federal Bureau of Labor Statistics reported that experience has shown the physically handicapped to be more efficient, to lose less time away from the job, to have more social contacts and to be less prone to accidents (except for the hard of hearing) than other employees.

Opinion about the ideal type of organization and sponsorship of rehabilitation programs varied. Rehabilitation centers supplementing hospitals and set up on a community basis were foreseen for the future by Deaver,⁷⁰ and the present lack of such centers was deplored by Rusk⁷¹ and various others. A co-ordinated rehabilitation bureau to serve the entire district of Lyons, France, was proposed as a model by Gauthier et al.⁷² That society has an undeniable responsibility toward the economic and social restoration of the handicapped was not disputed, but industry's share in this responsibility was questioned. Management's hesitancy to hire workers not in perfect health was considered valid by Luongo,⁷³ who pointed to the risks of subsequent unmerited compensation appeals, especially in cases of tuberculosis, silicosis and mental disorders. On the other hand, Pringle⁷⁴ expressed a broader concept of industrial health as indivisible into "health-at-home" and "health-at-work" categories.

The practical benefits in industry's employment of the handicapped were publicized by a number of organizations, such as the National Association for the Employment of the Handicapped and the Office of Vocational Rehabilitation of the Federal Security Agency.⁷⁵ It was estimated that approximately 8,000,000 men, including veterans and civilians, would require the services of rehabilitation and vocational-guidance centers.⁷¹ Yet, rather than increasing, the number of those applying to existing rehabilitation centers for training and jobs decreased.

A prerequisite in any industrial rehabilitation program is the co-operation of labor, industry, medicine and sociology,⁷⁶ but rehabilitation is primarily a function of surgical and medical care.⁷⁷ Close co-ordination between job assessor and physician is necessary, according to Lloyd,⁷⁸ who gave a detailed description of the job analysis method used in matching the rehabilitated worker to the job, as well as a rapid and practical system of re-

cording the analytical data. For workers injured in industry, Aitken⁷⁹ found that aftercare, with a view to the patient's re-employment, has been generally inadequate.

Attention was focused on the rehabilitation needs and potential productivity of persons disabled by specified illnesses or injuries: tuberculosis, cardiac conditions, rheumatic ailments and loss of limbs. Sander,⁸⁰ in a report on tuberculosis in industry, showed that it was unnecessary to refuse employment to job applicants with a history of this disease. He presented a guide for establishing the worker's clinical status and effecting proper placement and follow-up examinations. The difficulties encountered by persons with arrested tuberculosis were described by Moller.⁸¹ In workers with heart disease, the cardiac clinic and employment service should co-operate to appraise each patient's physical capacities, analyze the physical demands of the job and match the latter against the former.⁸² Sprague⁸³ advised complete cardiac studies of cardiac patients before employment is considered and regular reclassification checkups with the use of electrocardiography for those already employed. The training and placing in suitable work of rheumatic patients was discussed by Bonni,⁸⁴ and in another report the problem of dealing with injuries in workers affected by arthritic conditions was explored.

In the rehabilitation of civilians with amputations Kessler⁸⁵ stressed the lack of, and great need for, a program like that developed by the armed forces. The lack of such a service for persons disabled in industrial accidents was noted by Devesa⁸⁶ in Spain, where the patient is offered the alternative of a cash settlement or a prosthesis of poor quality and usually chooses the former.

PSYCHIATRY

Investigation in the field of industrial psychiatry suggested vast possibilities for the future. The urgent need for wider application of the psychiatric methods already proved and for further study and greatly expanded training programs was repeatedly stressed. Several surveys showed a direct relation between the mental and emotional health of workers and their proneness to frequent accidents, general unrest on the job — as evidenced in lateness and absenteeism — and even physical illness. Hence, attention to the psychologic impairment of employees was advocated as a cost-saving necessity for industry, if not as an obligation to the community.

Without proposing specific methods of administering psychiatric services, numerous spokesmen for industrial management and the medical profession urged consideration of human relations and of the emotional element involved in industrial employment.^{87, 88} Striking proof of the importance of psychologic factors in industrial efficiency was shown in a detailed study of the incidence of neuro-

sis in factory workers, the factors predisposing to it and its effects on production, reported in England⁸⁹ Of 3000 workers, 10 per cent had suffered definite neurosis and 20 per cent had suffered minor neurosis. Neurotic illness caused from a quarter to a third of all absence due to illness. The same frequency was found in workers at higher and lower levels of skill and earnings. The incidence was greater among women than men. The survey showed that neurosis was most common among workers with few social contacts and unsatisfactory domestic circumstances, and especially among those who disliked or were bored by their jobs. Fatigue, inadequate diet and lack of proper lighting on the job contributed to neurotic illness.

That mental incapacity in industry is related to group morale was established by Brodman and Hellman,⁵⁹ who found that frequent short illnesses occurred in departments where frequent lateness — a concomitant of poor morale — was also noted. The data further brought out that the individual's work morale is definitely influenced by the group and that different work groups have dissimilar morale.

Eliminating basic causes of employee maladjustment would do away with many grievances that start as minor complaints.⁹⁰ The role of the individual employee's supervisor or foreman in this type of adjustment was discussed by Brodman,⁹¹ Marrow,⁹² Maier⁹³ and others. Training programs were suggested to bring to first-line supervisors an awareness of, and ability to meet, the underlying complicated problems of emotionally disturbed workers.

Mounting concern for the costly effects of alcoholism among industrial employees was revealed in the growing number of studies on the subject. Bacon⁹⁴ estimated that of approximately 4,000,000 alcoholic persons in the United States, about 2,890,000 are men between the ages of thirty and sixty, and about 1,370,000 "chronic, excessive and compulsive drinkers are fairly regularly employed in industry." The problem is more susceptible to correction in industry than in the community at large and can be met with the help of psychiatry.

The industrial physician must bring himself up to date psychiatrically, according to Moorad,⁹⁵ who quoted statistics to show that from 85 to 90 per cent of accidents are due to "human factors." Healthy workers with personality disorders should be the responsibility of industry, for its own benefit. They not only have repeated accidents, Moorad declared, but also contribute heavily to absenteeism and project their dissatisfaction and low morale among their fellow employees. He described five prominent types, showing how and why each can cause accidents. The first step, in any case, is proper placement or elimination, but workers with neurotic tendencies should not be eliminated entirely, since cure and adjustment are possible through psychiatric treatment.⁹⁶ Patients with neurosis and employ-

ment difficulties have been rehabilitated with notable success at a unique industrial neurosis unit at Sutton Hospital in England.⁹⁷

Reports on various procedures used in placing and counseling employees indicated an increasing interest in this aspect of industrial psychiatry. The Rorschach (ink-blot) test is a valuable supplement to the customary testing and interviewing techniques. Noting that 1 out of every 11 employees have serious temperamental difficulties, Armbruster⁹⁸ held that job applicants should be tested not only for aptitude but also for interest in the work, motivation, general intelligence and temperament. The use of employee tests should be accompanied by an understanding of "the dynamic aspects of personality problems and of the complicated processes involved in group adjustment."⁹⁹

Counseling techniques were discussed by Himler,¹⁰⁰ who observed that "skilled listening constitutes the major part of the counselor's therapeutic armamentarium." In another report, industrial nondirective counseling was found to have advantages over clinical nondirective counseling, because of the more casual and intimate contact in the plant as compared to that found in clinical psychotherapy.¹⁰¹

Chronic industrial fatigue was seen as a contributing factor to emotional instability, absenteeism and proneness to accidents. The installation of "color conditioning," making scientific use of wall and fixture paints, was reported in several cases to result in less eyestrain and fatigue and greater efficiency,¹⁰² whereas noise control was given as another means of reducing mental fatigue and abnormal emotional reactions.¹⁰³ In discussing industrial fatigue, Carozzi¹⁰⁴ argued that more important than adapting machine and working conditions to the worker was attention to him as a human being, in his personal, family and broader social settings.

A notable step forward was seen in the inauguration of a pioneer program to train psychiatrists for the industrial-relations and labor field at Cornell University.¹⁰⁵ At the same time, at Harvard University and Massachusetts Institute of Technology scientific investigation was under way into the social — as distinguished from the physical — working environment of industrial employees.

EDUCATION

Educational facilities for physicians intending to enter the industrial service were extended here and there, by a few universities, and with the co-operation of certain local or state medical societies, hospitals and industries, but a general, standardized program was still lacking. However, progress was made in orienting individuals and organizations, both professional and industrial, toward accepting the inevitability of specialized industrial medical education. With emphasis shifting toward the preventive and research aspects of the field, there was

little question that more trained and experienced occupational practitioners were needed

Medical educators, in large measure, have failed to adapt their training or practice to meet the needs of the present-day American community, Kehoe¹⁰⁶ pointed out. No comparable field of medicine has offered so few opportunities for formal training as that of industrial hygiene.¹⁰⁷ Lacking specialized educational facilities, industrial medical directors "have evolved via the school of experience from general practitioners, general surgeons and internists," Brown¹⁰⁸ declared. Because well trained industrial medical men "are not to be found," he added, "there are an enormous number of small plants of every description without any medical department much less a health program."

There must be accord among industrial physicians, themselves, on the scope, objectives and methods of their practice, before teaching centers can be expected to provide the necessary instructional facilities, Buchan¹⁰⁹ asserted. Industry too "must make known in no uncertain terms its needs in medical and ancillary personnel, its needs in applied and fundamental industrial medical research."

According to several proposed plans, graduate work should include, as an essential, in-plant service or residency. One large industry's in-plant fellowship program, conducted with the co-operation of a leading medical school and said to be the first of its kind in this country, was described.¹¹⁰ In most of the graduate courses now offered, "a major defect is the lack of opportunity to give an adequate on the job experience."¹⁰⁷

In the undergraduate curriculum, Kronenberg¹¹¹ finds that "industrial medicine must be introduced and expanded if medical education is to be progressive and useful and meet present-day needs." Certain groundwork material can be introduced by "infiltrative tactics" in preclinical departments, Goldwater¹¹² stated, but industrial medicine, if regarded as a specialty, "obviously calls for special graduate or postgraduate training." He suggested that schools of public health were appropriate centers for training industrial physicians, as well as industrial nurses, engineers and chemists, and cited the inauguration of such a program at Columbia University. Among the nation's nine schools of public health, courses in industrial health and opportunities for advanced specialization in the field are generally provided.¹¹³

A crucial factor in the solution of the educational problem is the lack of established standards. Some progress was shown in the fact that residencies in the specialty of occupational medicine have been placed on a formal basis comparable to other residencies in line with the plan adopted by all certification boards.¹¹⁴ The chief difficulty remaining is to obtain suitable applicants and establish the fellowships themselves. From the viewpoint of the prospective candidates in the field of industrial medicine

both inducement and financial means were seen to be lacking.¹¹⁵ The failure of the medical profession to dignify industrial medicine with official recognition as a specialty was considered a deterrent to students in deciding to enter the field. Scholarship and fellowship funds are being established, and industry itself has been urged to subsidize graduate training.¹¹⁶

MEDICAL SERVICES

Marked inequalities persisted in the medical services provided for industrial workers in different localities and from one industry to another. In general, in-plant medical services were maintained and continually improved upon by large industries, but were still inaccessible to small industries. To what extent this disparity affects the whole picture can be judged by the fact that small concerns are estimated to constitute 99 per cent of the nation's industrial plants,¹¹⁷ employing about 60 per cent of the total labor force.¹¹⁸

No country-wide studies of the situation were reported on, but several surveys of limited groups of representative plants were made. One such study of 565 plants employing 500 or fewer workers showed that only a few provided even a minimum of medical care.¹¹⁷

In Illinois it was found that more than 12,000 small industrial establishments had no medical service,¹¹⁹ whereas in Connecticut,¹²⁰ 1400 plants employed a total of 119 physicians.

Diverse approaches to the small plants' health problem were recommended. In France¹²¹ small businesses affiliate to form a joint medical unit, a system successfully tried in one Pennsylvania community.¹²² Management-labor "safety committees"¹²³ have been organized in industries of all sizes in Sweden and also have functioned satisfactorily in some small or medium plants here.¹²⁴ In one plant of less than 1000 employees a single, full-time male nurse effectively directed the combined health, safety and welfare departments.¹²⁵ Regional programs were instituted, mostly advisory in character, in various centers such as Chicago,¹²⁶ and Washington, D. C.,¹²⁷ and in areas of Wisconsin,¹²⁸ Indiana¹²⁹ and Nebraska.¹³⁰

A total of 58 industrial-hygiene units were functioning under the Industrial Hygiene Division of the United States Public Health Service, with 43 per cent of the budget deriving from state and local funds and the remainder from federal funds.¹³¹

Among new types of service reported from abroad was that in Manitoba, Canada.¹³² An industrial-hygiene bureau, operating in a comparatively thinly populated region, attempted to improve the health conditions in small plants and conducted a program featuring portable x-ray equipment, plant surveys and stipple-cell counting service. For railway workers in France, four trains fitted with x-ray apparatus were traveling all over the country and

stopping wherever the equipment was needed for employees' periodic physical examinations¹³³

The extension of medical-service programs to all industries was urged not only on humanitarian grounds but also on the basis of increased production. On-the-job medical care was estimated to reduce absenteeism due to sickness up to 60 per cent¹¹⁷

The expansion of existing services in larger plants included the building of new dispensaries and the addition of various specialists to the medical-department staffs. Periodic physical examinations and special checkups for workers in hazardous areas were increasingly the custom¹²⁴

Heightened interest in industrial eye and dental programs was expressed^{125 126}. Teamwork of all those responsible for the employees' welfare was declared essential in the provision of health services. Derryberry¹²⁷ called on industrial physicians to realize "that the medical sciences are but a part of the total technology which must be brought to bear on the maintenance of health and the prevention of disease and disability."

The value of proper record keeping in industrial medical departments was frequently stressed and various suggestions for improved recording systems were offered¹²⁸⁻¹⁴¹

little question that more trained and experienced occupational practitioners were needed

Medical educators, in large measure, have failed to adapt their training or practice to meet the needs of the present-day American community, Kehoe¹⁰⁶ pointed out. No comparable field of medicine has offered so few opportunities for formal training as that of industrial hygiene.¹⁰⁷ Lacking specialized educational facilities, industrial medical directors "have evolved via the school of experience from general practitioners, general surgeons and internists," Brown¹⁰⁸ declared. Because well trained industrial medical men "are not to be found," he added, "there are an enormous number of small plants of every description without any medical department much less a health program."

There must be accord among industrial physicians, themselves, on the scope, objectives and methods of their practice, before teaching centers can be expected to provide the necessary instructional facilities, Buchan¹⁰⁹ asserted. Industry too "must make known in no uncertain terms its needs in medical and ancillary personnel, its needs in applied and fundamental industrial medical research."

According to several proposed plans, graduate work should include, as an essential, in-plant service or residency. One large industry's in-plant fellowship program, conducted with the co-operation of a leading medical school and said to be the first of its kind in this country, was described.¹¹⁰ In most of the graduate courses now offered, "a major defect

is the lack of opportunity to give an adequate on the job experience."¹⁰⁷

In the undergraduate curriculum, Kronenberg¹¹¹ finds that "industrial medicine must be introduced and expanded if medical education is to be progressive and useful and meet present-day needs." Certain groundwork material can be introduced by "infiltrative tactics" in preclinical departments, Goldwater¹¹² stated, but industrial medicine, if regarded as a specialty, "obviously calls for special graduate or postgraduate training." He suggested that schools of public health were appropriate centers for training industrial physicians, as well as industrial nurses, engineers and chemists, and cited the inauguration of such a program at Columbia University. Among the nation's nine schools of public health, courses in industrial health and opportunities for advanced specialization in the field are generally provided.¹¹³

A crucial factor in the solution of the educational problem is the lack of established standards. Some progress was shown in the fact that residencies in the specialty of occupational medicine have been placed on a formal basis comparable to other residencies in line with the plan adopted by all certification boards.¹¹⁴ The chief difficulty remaining is to obtain suitable applicants and establish the fellowships themselves. From the viewpoint of the prospective candidates in the field of industrial medicine

both inducement and financial means were seen to be lacking.¹¹⁵ The failure of the medical profession to dignify industrial medicine with official recognition as a specialty was considered a deterrent to students in deciding to enter the field. Scholarship and fellowship funds are being established, and industry itself has been urged to subsidize graduate training.¹¹⁶

MEDICAL SERVICES

Marked inequalities persisted in the medical services provided for industrial workers in different localities and from one industry to another. In general, in-plant medical services were maintained and continually improved upon by large industries, but were still inaccessible to small industries. To what extent this disparity affects the whole picture can be judged by the fact that small concerns are estimated to constitute 99 per cent of the nation's industrial plants,¹¹⁷ employing about 60 per cent of the total labor force.¹¹⁸

No country-wide studies of the situation were reported on, but several surveys of limited groups of representative plants were made. One such study of 565 plants employing 500 or fewer workers showed that only a few provided even a minimum of medical care.¹¹⁷

In Illinois it was found that more than 12,000 small industrial establishments had no medical service,¹¹⁹ whereas in Connecticut,¹²⁰ 1400 plants employed a total of 119 physicians.

Diverse approaches to the small plants' health problem were recommended. In France¹²¹ small businesses affiliate to form a joint medical unit, a system successfully tried in one Pennsylvania community.¹²² Management-labor "safety committees"¹²³ have been organized in industries of all sizes in Sweden and also have functioned satisfactorily in some small or medium plants here.¹²⁴ In one plant of less than 1000 employees a single, full-time male nurse effectively directed the combined health, safety and welfare departments.¹²⁵ Regional programs were instituted, mostly advisory in character, in various centers such as Chicago¹²⁶ and Washington, D. C.,¹²⁷ and in areas of Wisconsin,¹²⁸ Indiana¹²⁹ and Nebraska.¹³⁰

A total of 58 industrial-hygiene units were functioning under the Industrial Hygiene Division of the United States Public Health Service, with 43 per cent of the budget deriving from state and local funds and the remainder from federal funds.¹³¹

Among new types of service reported from abroad was that in Manitoba, Canada.¹³² An industrial-hygiene bureau, operating in a comparatively thinly populated region, attempted to improve the health conditions in small plants and conducted a program featuring portable x-ray equipment, plant surveys and stipple-cell counting service. For railway workers in France, four trains fitted with x-ray apparatus were traveling all over the country and

CASE 35131

PRESENTATION OF CASE

A thirty-six-year-old woman, a clerk, entered the hospital with a chief complaint of increasing constipation.

Six years prior to admission, because of right-lower-quadrant "gripping" pain and abdominal signs (details unknown), she had an exploratory laparotomy, with excision of a right ovarian cyst and a normal appendix. For two years following this procedure she was asymptomatic, but then the right-lower-quadrant pain began to recur several times a week. Two years before admission she began to notice midsacral pressure discomfort at the time of her menstrual periods, with partial relief by bowel movements. During the year before entry she had occasional sharp left-lower-quadrant pain with her menses. One and a half years before admission, for a period of five days, she had very black vaginal bleeding followed by her usual menstrual flow, and four months later three episodes of vaginal bleeding in one month. Otherwise, the menstrual periods were regular, occurring every twenty-four to twenty-six days and lasting five days, with a normal quantity of flow containing some clots. For two years prior to admission she was increasingly constipated, except that at the time of the menstrual periods, the stools were very loose and occasionally quite dark, but never black or bloody. She had some mild gaseous indigestion, without specific food intolerance or relation to meals. There was no anorexia or weight loss, and the system history was not remarkable. During the year and a half before admission three barium enemas were done elsewhere. The last two of these examinations allegedly showed a polyp in the sigmoid.

Her mother had diabetes and a mastectomy (diagnosis unknown) had been performed.

Physical examination disclosed a normally developed and well nourished woman in no discomfort. There was a well healed right-lower-quadrant paramedian scar. To deep pressure there was tenderness in the right upper and both lower quadrants, with the maximal tenderness in the right lower quadrant.

The sigmoid was palpable in the left lower quadrant and was moderately tender. There was no distention, and peristalsis was normal. Pelvic and rectal examinations were entirely negative.

The temperature, pulse and respirations were not remarkable. The blood pressure was 110 systolic, 70 diastolic.

The urine examination was negative. The hemoglobin (photoelectric-cell technic) was 14.5 gm, and the white-cell count was 7500. A blood Hinton test was negative. A barium enema demonstrated a rounded, filling defect, 2 cm in diameter, in the sigmoid at the junction with the descending colon.

FIGURE 1

The bowel in the immediate vicinity of the defect was smooth in contour, and the lumen was narrowed (Fig 1 and 2). There was some suggestion that with pressure, a change in the defect could be produced. Following evacuation, air was injected into the large bowel in an attempt to disclose any other polypoid defects. No other definite masses were made out, although at about 8 cm from the lesion described there was a questionable defect, about 5 mm in diameter, in the bowel that was partially outlined with barium. The remainder of the colon was not unusual.

After preparation with sulfasuxidine by mouth, an operation was performed on the fifth hospital day.

DIFFERENTIAL DIAGNOSIS

the colon was done in this patient. Whether or not a hysterectomy should have been done as well would have to be determined by the findings at the time of operation.

DR LELAND S. MCKITTRICK. Dr Welch has been very logical as well as practical in his reasoning. Dr West, the resident, also made a preoperative diagnosis of endometriosis on this patient. When the abdomen was opened I did not know what it was. I thought it was carcinoma. The lesion was just as hard as it could be. It had a characteristic appearance in the gross of a small, constrictive, scirrhous type of carcinoma, with an epiploic appendix adherent over the top of it. During the course of the resection Dr Risley, who was helping me, called attention to a small nodule along the bowel, about 6 or 7 cm from the primary lesion. This was a whitish, hard area, probably 3 mm in diameter, which looked for all the world like a carcinomatous implant. It did not have the color that one associates with an endometrial implant, and that led us to think that this was probably carcinoma rather than endometrioma. So we broadened the amount of bowel we took out. We took out more bowel than I would have taken out if I had been confident of the diagnosis when we operated because I honestly thought that we were dealing with carcinoma of the sigmoid. The patient did have a cystic tumor or mass, about 6 cm in diameter, on the left ovary that no one had felt prior to operation. She did not relax too well, I think that would have been felt if she had been examined under anesthesia or had relaxed well.

CLINICAL DIAGNOSIS

Carcinoma of sigmoid

DR WELCH'S DIAGNOSIS

Endometrioma of sigmoid

ANATOMICAL DIAGNOSIS

Endometriosis of sigmoid

PATHOLOGICAL DISCUSSION

DR CASTLEMAN. The lesion that Dr McKittrick described in the upper sigmoid presented on the serosa as a puckered, white, constricting process, which on section was seen to extend deep into the muscularis. It was grayish white and fibrous rather than granular as is seen in carcinoma. The mucosa over it was normal. The lesion measured about 3 by 2 by 1 cm, and microscopically was characteristic of endometriosis.

The microscopical section (Fig 3) showed how deep the endometrial glands had extended into the muscle layers. In a few foci the process was very close to the mucosa. A few centimeters above this lesion was another smaller one, which corresponded to the upper defect seen on the roentgenogram. There are, as Dr Welch stated, some surgeons who

believe that even if the patient is known to have endometriosis, the bowel should be resected in the presence of obstruction. Three years ago at these exercises in the discussion of a case of endometriosis, I made the statement that when endometriosis involves the sigmoid, resection has often been necessary.* Dr James R. Miller, of Hartford, wrote in and questioned the need for resection of the bowel for endometriosis, believing that castration would produce regression of the sigmoid lesion. I agree that this probably would occur in some cases,

FIGURE 3 Photomicrograph of Sigmoid, Showing Endometriosis in the Muscularis Close to Edematous and Fragmented (Artifact) Submucosa

but in a case like this, with the disease extending so deep, it may be too late. Then there is the point that Dr Welch makes that after the menopause the lesion may constrict even more.

Have you had any experience with that, Dr McKittrick?

DR MCKITTRICK. The first one I did was on a woman sixty-five years old. I do not believe the ovaries were doing much functioning, and she was operated on because she was obstructed. But going back to the case we are discussing, I believe that if I were in this woman's place I would rather have ovarian tissue and have had a segment of bowel resected than to have the bowel not resected and be sterilized at thirty-six years of age.

DR CASTLEMAN. As long as you could do an end-to-end anastomosis.

DR MCKITTRICK. That is correct. This patient had not had much discomfort. She was only thirty-

*Case Records of the Massachusetts General Hospital (Case 32321). *New Eng J Med* 235:199-201, 1946.

DR STANLEY M WYMAN On all the films there is a constant, round, smooth defect overlying the brim of the pelvis in the wall of the ascending colon, near the junction of the sigmoid. This filling defect appears perfectly smooth, and there appears to be a preservation of the mucosa over the lesion. On some of the spot films it has a suggestion of a hook, proximally and distally, that we see with intramural, extramucosal lesions. This film has a suggestion of a small, less definite mass just above the primary mass on the opposite wall of the bowel, but it is not well seen on all films, although it is seen on this large film of the colon. I should prefer to call this

FIGURE 2

an intramural extramucosal mass rather than a polypoid tumor of the colon, although one cannot be entirely certain.

DR WELCH I think the discussion of this case will be more interesting if I make a diagnosis first and then attempt to support it by the data we have. This ought to be an endometrioma of the sigmoid. If it is not, it still should be.

Let us go back over the history to see whether we can substantiate that diagnosis. At operation six years before entry a right ovarian cyst and a normal appendix were excised. Two years thereafter the patient was asymptomatic, but then the right-lower-quadrant pain began to recur. The next question arises, Could the pain have been associated with the lesion now discovered in the sigmoid? I am inclined to think that it was not pain in the right lower quadrant associated with sigmoid disease. This type of pain has been described frequently,

but the right-lower-quadrant pain from primary sigmoid disease is usually due to distention of the cecum from a constricting lesion in the sigmoid or from a contiguous, inflammatory spread from an inflamed sigmoid that has prolapsed over into the right lower quadrant. There is no evidence of distention or inflammation of the bowel, and so I assume that there was something else in the right lower quadrant. She may have had excision of an endometrial cyst at the first operation, with retention of a portion of the ovary, and again some endometriosis had developed in the remaining portion. It is surprising to find that she did not have more menstrual pain, this would indicate, if this diagnosis is correct, that endometriosis in the pelvis was not terribly extensive. The black bleeding suggests that she had adenomyosis of the uterus as well.

I assume that a proctoscopy was done and was negative.

DR BENJAMIN CASTLEMAN That is right.

DR WELCH I assume that there was no actual bleeding from the rectum at the time of the period. That might be of interest to know. Endometriomas rarely involve the mucosa, but occasionally do, with bleeding by rectum. The defect in the sigmoid on x-ray examination is perfectly compatible with this diagnosis. We have had in this hospital several lesions in the lower descending colon or upper sigmoid at this level that have been endometriosis. Interestingly enough, some have not become symptomatic until after the menopause. I suppose the increasing fibrosis that takes place after atrophy of the endometrial tissue produces obstruction. This lesion can be assumed to be still active, and the increase in symptoms at the time of the periods is explained by the congestion that occurs in the tumor. Endometriomas in the gastrointestinal tract are found chiefly in the sigmoid or on the surface of the appendix and very rarely in the lower ileum or cecum. The position of this lesion is consistent. The negative pelvic examination indicates that disease in the other pelvic viscera is minimal.

I imagine the surgeon on entering the abdomen was confronted with a minor amount of endometriosis in the ovaries, a small segment of remaining right ovary and a lesion in the sigmoid, about which it was impossible to tell the exact nature. The statement has been made in the literature that when endometriosis is the diagnosis the patient should preferably be treated by sterilization, after which the lesion will atrophy and the dangers of bowel resection will be avoided. That, I assume, was not carried out in this case for two reasons. In the first place, no one knows what the lesion is, and even if atrophy of the endometriosis did occur, there is so much involvement of the sigmoid that it is likely to progress to obstruction later on. Consequently, I assume that a resection of

The diagnosis of gastric ulcer was not sustained when a probably adequate examination of the stomach was made. A duodenal lesion was demonstrated after admission to the hospital. Therefore, we can put a question mark against the original suggestion of gastric ulcer. If he did not have gastric ulcer, which always means that the ulcerating lesion may be cancer, we can focus our attention on the biliary tract as the basis of the symptoms three months before admission. The x-ray film, which I have not seen but would like to see shortly, was certainly entirely consistent with biliary disease. He could have had a stone either in the gall bladder — with a resulting gall-bladder infection and an acute cholecystitis, in addition to a cholangitis — or in the common duct with a ball-valve action and jaundice with an attack. That diagnosis is tenable only to a certain point and may fail to explain what subsequently happened. He had lost 26 pounds in weight in the presence of diminishing jaundice. As far as I can tell from the history, there was no particular pain or discomfort associated with it. He did not vomit. There is no explanation given for this loss of weight, but it is a striking fact observed over a relatively short period. If he had had fever, one could explain the loss of weight on that basis. Certainly, an attack of biliary colic due to stone three months previously should not produce a 26-pound weight loss, without continuous or added symptoms.

Physical examination again directs attention to the biliary tract, and the statement is made that several examiners felt a tender, firm, smooth mass. It is not said whether the mass was lobular or round, which one would like to know. The mass was felt in connection with the liver below it. It moved with respiration, and everyone thought it was a palpable gall bladder. A palpable gall bladder in the absence of jaundice immediately following an acute attack of biliary colic can be due to hydrops with stone in the ampulla of the cystic duct. It very frequently occurs as a transitory phenomenon, present for a few hours and then disappearing as the stone moves. A gall bladder palpable three months after the only attack of biliary colic probably should be explained on some other basis. This is not a good example of Courvoisier's law in the sense that it cannot be described with painless jaundice. The jaundice nearly disappeared, and there was no pain for three months. He had

not had anything else for three months. The jaundice was out of the picture except at a minimal degree. At the present time one can at least invoke Courvoisier's law and try to play with it a bit in this sense. Here was a patient with a palpable mass thought to be gall bladder, and he had jaundice. That should mean ordinarily a pathologic gall bladder and obstruction at the ampulla of the common duct. That is the real meaning of Courvoisier's law. Usually the obstructing lesion is cancer of the head of the pancreas or of the ampulla or of the bile duct. The burden of proof is usually on the man who says it is not carcinoma. Rarely, we do have a palpable gall bladder in the presence of jaundice due to common-duct stone. It is very uncommon, although we have a few cases as every hospital has.

In this case there may be plugging of the duct due to a growth. There may be external pressure, let us say from a malignant lesion, which is causing marked lymphadenopathy with obstruction of the common duct at a certain level. The evidence that he had infection in the liver itself, I would say, is negligible. He could have had pain and jaundice with acute epidemic hepatitis. That is fairly common. The jaundice could persist for three months, but he should not have had a palpable gall bladder, and the liver-function tests should not have been as described in this case. He should have had a high cephalin flocculation, high thymol turbidity and a low white-cell count rather than a high one, and the differential should not have been normal. It does not seem logical to interject that possibility into the picture at all. Therefore, it seems to me that we have a right to consider one of two things without observation of the x-ray films at the moment: either a gallstone with or without a stone in the common duct, which I think is relatively unlikely, or a malignant lesion in the region of the ampulla of Vater, in the pancreas, in the ampulla itself, in the bile duct with gradual spread to the adjacent areas or even in the gall bladder.

My own belief at this stage is that the patient had neoplasm in the neighborhood of the ampulla as well as gallstones, and I am sure he ought to have been explored on the basis of this protocol alone.

I should like to see the x-ray films. They can modify the diagnostic possibilities but not the approach that should be taken.

DR JOSEPH HANDELIN: The initial examination, a cholecystogram, shows a nonfunctioning gall

six, and her right ovary and tube had been taken out. She was young, I think, for one to go ahead and do a complete castration job unless it had been necessary to do so. It seemed to me that if she progressed along reasonably well, the longer a definite operation was postponed the more freedom we would have to do the thing when it had to be done. She has convalesced and gone home.

CASE 35132

PRESENTATION OF CASE

A fifty-year-old man was admitted to the hospital because of jaundice and a weight loss of 26 pounds.

Three months before admission he had an attack of severe, sharp, right-upper-quadrant pain, radiating to below the right scapula. This pain was crampy and was accompanied by distention. He was hospitalized and in the course of a few days became jaundiced. X-ray films at this time are said to have shown a nonfunctioning gall bladder and a gastric ulcer. In the two months preceding admission to this hospital the intensity of the jaundice gradually decreased. He lost 26 pounds in weight during this period.

The patient had had indigestion relieved by either food or water since boyhood. Twelve years before admission a perforated duodenal ulcer was sutured, and since then he had followed a strict dietary regime. He continued to have "ulcer pains," but there had been no hematemesis or vomiting. Eight years before admission he was hospitalized for "stoppage of the bowels" relieved by laxatives and enemas.

Physical examination showed faint jaundice still present in the scleras. The heart and lungs were normal. There was a smooth, firm, tender, movable mass, about 3-4 cm in diameter, in the right upper quadrant, which descended with respiration. This was thought by all the examiners to be the gall bladder. The liver was not palpable.

The temperature, pulse and respirations were normal. The blood pressure was 130 systolic, 90 diastolic.

Examination of the urine revealed a specific gravity of 1.022, a + test for albumin, negative tests for sugar and diacetic acid and a +++ test for bile. Examination of the blood disclosed a hemoglobin of 12.2 gm and a white-cell count of 13,300, with a normal differential. The nonprotein nitrogen was 23 mg per 100 cc, and the total protein 7.35 gm (albumin-globulin ratio of 1.8), the serum bilirubin was 4.1 mg per 100 cc direct and 4.6 mg indirect, and the alkaline phosphatase 28.9 mg. A cephalin flocculation reaction was + in twenty-four and ++ in forty-eight hours, and the thymol turbidity 3.0 units. A blood Hinton test was nega-

tive. A gastric analysis showed free hydrochloric acid and a negative guaiac reaction.

A Graham test demonstrated failure of the gall bladder to fill. In the right upper abdomen there was a dense calcification, 1.0 cm in diameter, that was consistent with a stone in the gall bladder or common duct or mesenteric lymph node. A cluster of calcifications, probably in the pancreas, was also noted. A barium enema was negative. A gastrointestinal series was done. The stomach was pliable, and its mucosal pattern within normal limits. The patient permitted little palpation in this region, but no ulceration or filling defects were demonstrated. The duodenal bulb was deformed in a manner consistent with previous surgery. There was an irregularity of the lesser curvature and of the duodenal loop about which no opinion was given.

On the eighth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR CHESTER M JONES. This is the sort of case in which a precise diagnosis is interesting but unimportant. The important thing is the decision what to do, and the sooner that decision is made, the better. One may make an intelligent guess that is logical but a mistaken diagnosis. The past history was that of ulcer with perforation twelve years before admission. The perforation was probably closed successfully. The duodenal-ulcer problem remained. Closure does not solve that problem at all. The episode eight years prior to admission, which was called intestinal obstruction and which responded easily to simple methods and did not recur, is not pertinent to the present discussion. The subsequent history of prolonged change in the bowel habit, I judge, was due to fecal impaction.

That leaves us with a man of fifty years with a three-month history initiated by right-upper-quadrant pain, which is in the classic location for gallstone colic. The pain radiated through to the right scapula, following which he was jaundiced. On the basis of the story alone and in the absence of other demonstrable facts, there is no reasonable doubt that he had biliary colic. The fact that a gastric ulcer was said to have been demonstrated at this time is interesting, but it is hearsay evidence. It may have been a faulty interpretation. It would not be the first time that a gastric deformity, even one that persisted for an unusual period, was not found at exploration, but at operation gallstones were present. In other words, for some reason or other, gall-bladder disease associated with stones can occasionally produce a constant gastric deformity that is indistinguishable from cancer or ulcer. It is very uncommon but it does occur, and I can think of several important cases here in which the diagnosis prior to operation was gastric cancer and at operation we found only gallstones.

seeped in, which surely suggests disease of the gall bladder

CLINICAL DIAGNOSES

Cholelithiasis, with common-duct stone

Peptic ulcer

DR JONES'S DIAGNOSES

Gallstones

Cancer of biliary tract, probably of bile duct

ANATOMICAL DIAGNOSES

Adenocarcinoma, Grade II, of head of pancreas, with metastases to peritoneum, liver, gall bladder, regional lymph nodes ileum, stomach and lung

Chronic pancreatitis

Ascites

Common-duct stone

Cholecystgastrostomy, recent

PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY At exploratory operation the peritoneal cavity was immediately found to be studded with cancer metastases, as was the surface of the liver. Because of adhesions in the region of the stomach and duodenum, it was impossible to carry out an extensive exploration, but the surgeon was under the impression that the head of the pancreas felt like cancer and on that basis did a cholecystgastrostomy.

DR JONES Did he describe the gall bladder?

DR MALLORY It was distended. It is not stated to what degree, however. The patient lived only four weeks after operation. At the time of autopsy we found extensive cancer of the head of the pancreas and also very extensive chronic pancreatitis involving all the rest of the organ and, I think, explaining by means of fat necrosis the calcification that the x-ray examination showed in the body of the pancreas. There was a stone in the common duct a few centimeters up from the ampulla, as Dr Jones predicted. The ampulla was quite free, for when the stone was removed, the common duct opened unobstructed into the duodenum. The jaundice, I believe, was due to the gallstone, not to the carcinoma. Between the time of operation and the autopsy the tumor had extended to some extent and now involved the serosa of the gall bladder and the stomach but was evidently not primary in either place. We could not find any trace of the old duodenal ulcer.

DR JONES Was the liver enlarged particularly?

DR MALLORY Slightly, not greatly.

DR HANELIN Was there any fluid in the lesser peritoneal sac?

DR MALLORY About 500 cc in the general abdominal cavity, not in the lesser peritoneal space. There was a small, fluid-filled area immediately adjacent to the midportion of the pancreas in the retroperitoneal tissues. It contained only 30 cc of fluid. There were also some carcinomatous implants on the serosa of the stomach.

bladder and a calcium density, 1 cm in diameter, in the upper abdomen. In addition, there are multiple punctate calcifications, which extend from the right aspect of the second lumbar vertebra upward and to the left. These are very likely pancreatic calcifications. The larger calcified density in the upper abdomen is seen to overlie the spine and may represent a stone that had its origin in the gall bladder. It is situated somewhat higher and more medial than the usual position of the gall bladder so that it might be within the cystic or common duct.

DR JONES It is fairly high to be in the ampulla, it is at the first vertebra, is it not?

DR HANELIN Yes

The barium enema shows no evidence of intrinsic or extrinsic colonic abnormality. There is an interesting shadow visible in the right upper abdomen, which may be of importance. It is superimposed upon the liver and kidney and may represent the clinically palpable mass. Films of the upper gastrointestinal tract show no intrinsic abnormality of the stomach. The duodenal bulb, however, is deformed in a manner characteristic of chronic ulcer.

DR JONES In addition to the effect of surgical operation

DR HANELIN It is difficult to be certain to what extent surgery contributes to this deformation. The second portion of the duodenum is displaced toward the midline and is indented along its lateral aspect. There is also a suggestion of a smooth pressure defect along the lesser-curvature aspect of the stomach.

DR JONES It could be the left lobe of the liver.

DR HANELIN Yes, that is its usual location.

DR JONES In other words, there is no evidence of a gastric lesion, which I think is of some importance. There is an abnormality here that has to be taken into account. It could be a gallstone that would have to be in the upper part of the common duct or, as Dr Hanelin said, in the cystic duct near its junction but not near the ampulla. It would be high for that. This is the region of the first lumbar vertebra, and usually the ampulla is at the junction of the second and third lumbar vertebrae. Is that correct?

DR HANELIN That is correct. A tumor of the head of the pancreas, if large enough, should en-

croach upon the second portion of the duodenum from its inner aspect.

DR JONES In addition, something of interest that does not help in the diagnosis is the appearance of the fine calcification in the region of the body of the pancreas. It may well be pancreatic calcification. It does not explain the entire history to me, although calcification of the pancreas may be associated with repeated attacks of pain, jaundice, fever and loss of weight. To be sure, this is the first attack, but I doubt very much if we could do more than say that there may be some disease of the pancreas that has caused calcification but is not the cause of the symptoms. In my mind, it has no significance as far as the presence or absence of cancer is concerned. If I understand Dr Hanelin correctly and interpret these films correctly, there is no evidence of involvement of the duodenum by compression from a cancer of the pancreas.

DR HANELIN That is correct.

DR JONES The duodenal loop is not compressed from the inner side, suggestive of pancreatic disease. It might suggest something external to the duct or absolutely contiguous with the duct, possibly arising there or within the gall bladder. I should say that the suggestion that Dr Hanelin made that there is some pushing of the duodenum toward the midline is much more evidence of tumor. It does not give any idea of the nature of the tumor. Therefore, I am left where I was before I saw the x-ray films. I believe he had a gallstone and some other disease in addition. I do not believe that pancreatitis alone will explain it. I would expect to find cancer, probably of the duct itself or of the ampulla, possibly of the gall bladder. I should be very much surprised if he had only stones in the common duct and nothing else. He certainly should have been explored in the hope that that might be the case and, lacking that, in the hope that cholecyst-enterostomy of some sort might permit palliation of a more serious condition and possibly resection of the tumor.

The other thing I did not comment on was the second x-ray finding of a nonfilling gall bladder. With jaundice it is not surprising that the gall bladder did not fill. With diminishing jaundice the result of the second Graham test should have been anticipated. Nothing was said about the stools. If bile were going through, some dye might have

bones of contention. The other two strike closer to the meat of the matter.

One alleges that Dr. Van Waters failed to provide the prisoners with good examples by hiring former inmates as staff members. The Board called the charge "irresponsibly made" and added "The example afforded by such persons, showing that it was possible to make good despite handicaps and errors, could be an important factor in the rehabilitation of other inmates."

The fourth, and possibly the most significant, group of charges accused Dr. Van Waters of violating state indenture laws by allowing inmates to be employed in other than domestic capacities. These laws were drawn up some seventy-five years ago. They specified that prisoners could work only as domestic servants. Since there were extremely few occupations open to a working woman in the 1870's, those laws are now inordinately restrictive. The board found that a fair amount of leeway in this respect had been allowed by former commissioners. It decided that the responsibility was theirs.

Commissioner McDowell once commented, "There can't be one law for great penologists and another for the rest of us." True enough. But laws are seldom changed until someone is courageous enough to test them and find them wanting. In a progressive society the letter of the law ever lags behind its spirit. Often enough, those who adhere too strictly to statutes whose origins are fundamentally humanitarian are left groping in the backwash of progress with nothing to guide them but a dusty law book.

Clearly, Dr. Van Waters is ahead of the law. She has no use for the punitive aspects of prison life. She believes that enforced incarceration as an end in itself embitters more than it educates.

She calls her charges "students." Their troubles receive psychiatric attention, and the institution officers are their confidantes. They were encouraged to seek gainful employment in occupations of their choice and in line with their talents. Her entire program was geared to the principle of preparing the inmate for a successful return to the community.

She and others should be allowed to proceed on this principle. Nothing in the law should impede the temperate operation of the methods she has done so much to advance. Salaries should be raised

to attract more persons of Dr. Van Waters's stature (both as institution heads and as commissioners of correction). The responsibilities of prison heads should be more clearly defined. The indenture laws should be liberalized. Even use of the term "indenture"—with its implications of bondage—might well be abandoned.

Let society catch up with Miriam Van Waters! That is indeed a challenge.

NEW PROGRAM IN PHYSICAL MEDICINE AT COLUMBIA

IN MAY, 1944, Bernard Baruch made a grant of \$400,000 to Columbia University to aid in the development over a ten-year period of a model center for teaching and research in physical medicine as recommended by the original survey by the Baruch Committee. Under the guidance of a committee on physical medicine of the medical faculty this project developed with signal advance in the therapeutic application of physical medicine, particularly including rehabilitation, and in education of technicians in physical and occupational therapy and of physicians training to specialize in the field. Some important basic research particularly in physiology has also been instigated.

This program has enlarged to such an extent that it includes the Columbia Presbyterian Medical Center, the Institute of Crippled and Disabled and eight other hospitals in New York City. In 1947 nearly 200,000 physical-therapy and occupational-therapy treatments were given in the medical center alone. To keep pace with this growth a new program has been announced by President Dwight D. Eisenhower. Dr. Robert C. Darling, associate professor of medicine at the College of Physicians and Surgeons, will serve as co-ordinator of physical medicine and rehabilitation, as well as director of research, a post he has filled for the past three years.

With the world-known rehabilitation facilities of the Institute of Crippled and Disabled and the wealth of clinical opportunities at Presbyterian and affiliated hospitals, together with a well co-ordinated research program, one should indeed anticipate at Columbia a model center for training and research in physical medicine.

JUSTICE AND THE LAW

IN SCIENCE as in sociology the words of St. John "And ye shall know the truth, and the truth shall make you free," have particular significance, for on them depends the direction in which mankind will move during the coming years. Massachusetts has now on the record two recent celebrated cases the final outcome of which will depend upon the degree to which truth can be served.

The first of these, the stand of the medical profession against the antivivisectionists, although still unsettled, has already spotlighted certain aspects of scientific progress. The second, Dr. Miriam Van Waters's fight for reinstatement as head of the Framingham Women's Reformatory, will, it is hoped, have educated the public in the ways of humane and progressive penology.

It is regrettable that public scrutiny should have been fixed on Dr. Van Waters's methods in such an atmosphere of malicious sensationalism. Whatever their motives in bringing the twenty-seven preposterous charges of "misconduct in office" against one of the foremost sociologists of our time, it seems evident that Commissioner of Correction Elliott E. McDowell and possibly others in penologic and political circles had a score to settle with Dr. Van Waters. Fortunately they failed, she stands completely vindicated, and her accusers are utterly discredited.

Parenthetically it may be added that not so many years ago Massachusetts lost the services of another able penologist, Howard B. Gill, who was ousted as head of the Norfolk Prison Colony, where McDowell was supervisor of workshops before he became commissioner last year. At that time, however, there was no state law giving public officials the right of appeal. Howard Gill stayed fired.

Dr. Van Waters served happily and successfully under five commissioners for sixteen years before McDowell was appointed. She filled well the shoes of such enlightened predecessors as Clara Barton and Mrs. Jessie Hodder. Her work has made Framingham one of the most studied and emulated penal institutions in the world.

Three months after he assumed office McDowell ordered the investigation of the reformatory. He had already indicated his hostility to her methods. The tactics employed during the inquiry were questionable. The charges revealed the spite and lack of vision of her accusers. They may be divided roughly into four categories, two of which may be dismissed without discussion.

One comprises accusations that Dr. Van Waters failed to stop sexual perversion among inmates. The review board appointed by the Governor found that everything possible had been done to contain a problem that exists in every situation where the sexes are segregated. The other includes a grab bag full of picayune charges, none of which were found to be just cause for removal.

These two groups of reasons seem to have been simply an attempt to justify the dismissal. They have little bearing on what appear to be the main

amply demonstrated by the sad fate of the Nazi Medical Corps, and there can be no quarrel with the deferment of men already embarked on a medical career. Whether we are fated to live through a long cold war, another hot war or no war at all, they will be needed. It was presumably at this point in their thinking that National Headquarters issued Memorandum No 7.

But thinking need not stop there. The question is not the deferment of medical students but the deferment of "premedical" students. Granted that medical training is long, will a college freshman who is eighteen months older for having done his military service be, for that reason, deterred from following the career for which he believes himself best fitted? And, more important, can an eighteen-year-old boy be counted on to evaluate maturely his motives for calling himself "premedical" and accepting draft deferment? Certainly a youthful desire to escape the draft would be an inadequate and unfortunate motivation for the support of a life-long career in medicine — a career, by the way, that will not and should not exclude the possibility and the duty of later military service.

The decision arrived at by the Harvard Faculty is surely foresighted and sound, and it is hoped that a similar clarity of thought and sincerity of purpose will guide the rest of the medical faculties in resolving the serious issue that Memorandum No 7 has placed before them.

MASSACHUSETTS MEDICAL SOCIETY

TREASURER'S REPORT COVERING REFUND DISTRIBUTION

The Treasurer of the Massachusetts Medical Society makes the following report regarding the refund to the district societies for 1949.

The Council voted to distribute the sum of \$8000 00 to district societies. The total number of payments of annual dues received by the Treasurer by March 1, to be counted for the refund, was 4647. Therefore, the refund to the district societies for each paid fellow is \$1 72.

The following table gives the number of payments, as of March 1, and the refund to each district as of March 9.

DISTRICT	NUMBER REPORTED PAID	REFUND
Barnstable	44	\$76 07
Berkshire	126	217 12
Bristol North	60	103 59
Bristol South	197	339 24
Essex North	181	311 72

THE \$25 00 ASSESSMENT

On March 1, 1949, I sent the American Medical Association \$50,000 as the first installment of the contribution of the membership of the Massachusetts Medical Society to the Campaign of Education. This represents payment of the assessment by about a third of our members. The checks are coming in to this office every day in a rather constant flow. One thousand checks were received within two weeks after the bills were mailed.

A description of the method we used here was sent to the other New England states and I have received word from them that they are all co-operating in this effort. The Washington State Medical Association has made the assessment compulsory, and I know of no other state society that has done so. Some states have increased their own dues for this public-relations effort. Michigan has done this for four years and has accumulated a fund of \$400,000 to use in educating the public in that state concerning the nation's health.

I have received some checks for more than \$25 00. A few checks have been for less than the amount asked because of personal financial difficulties. Only 12 fellows have written to say that they will not pay. Many more letters have been received praising this worthy effort.

It is my hope that by the end of March we shall have received checks from nearly 100 per cent of our members.

H. QUIMBY GALLUPE, *Secretary*

Dr Darling, the new co-ordinator, a graduate of Harvard Medical School, served as assistant director of the Fatigue Laboratory at Harvard and also as a consultant to the Quartermaster General. His studies have particularly dealt with various aspects of physical fitness, and he recently rendered a report on this subject in the *Journal of the American Medical Association* as chairman of the Baruch sub-committee on physical fitness. The organization of such a strong program in physical medicine at Columbia should attract competent young physicians into this rapidly growing and important field of medicine.

CANCER OF THE LUNG

OVERHOLT and Schmidt, in their paper on survival in primary carcinoma of the lung, delivered at the annual meeting of the New England Surgical Society last October and published elsewhere in this issue of the *Journal*, have made a valuable contribution to the increasing knowledge of cancer.

Improvement in the operability rates and in the operative results are encouraging but are to be expected, particularly in a branch of surgery that has been so recently developed as has been surgery of the lung. Less encouraging and presenting, indeed, a distinct challenge to both medical practice and medical public relations is the time that still elapses between the first symptom experienced by the patient and the establishment of the diagnosis.

This tragic interlude averaged eleven and three-fourths months for 133 patients who were seen between 1932 and 1942. Three months elapsed before the patient visited the doctor, another three months passed by before the first x-ray examination was made, and still another *five and three-fourths months* were lost before the diagnosis was made. Since 1942 this long interval has been reduced only to ten months. The doctor is now not consulted for three and eight-tenths months, the first x-ray examination is made one and six-tenths months later, and four and six-tenths more precious months elapse before the diagnosis is established.

This total interval can conceivably, be completely eliminated by the same type of radiologic screening of the population that is now employed in tuber-

culosis case finding, for the growth can usually be discovered by the experienced radiologist or chest specialist before it begins to produce symptoms. Notice of abnormal areas of density spotted in survey films is reported back to the referring physician. It is his responsibility to see that any silent, abnormal density is properly labeled. His patient may have a silent, primary cancer of the lung, which, in most cases, is localized and can be treated successfully then, but not later.

Cancer of the lung should carry the highest rates of cure of any type of internal cancer because the time schedule of discovery can be set ahead to anticipate symptoms. The responsibility is threefold: support by the laity of mass screening of the adult population on an annual basis, proper sorting of areas of silent abnormal densities by the medical profession generally, and reliance on exploratory thoracotomy in suspected cases.

UNWISE DRAFT DEFERMENT

ACCORDING to a recent release from the University News Office, the Faculty of Medicine of Harvard University has decided to continue its present policy of certifying for Selective Service deferment only students who are eligible to enter medical or dental school in the fall of the current year. Under the provisions of Local Board Memorandum No 7 of National Headquarters, Selective Service System, the faculty was empowered to certify men in their first and second years of college by regarding them as premedical students and by provisionally recording their names for admission to future medical studies. The refusal to avail itself of this power represents a wise and honest decision on the part of the Harvard faculty.

A similar decision has been reached by a few other outstanding schools, notably, Boston University, University of Cincinnati, Johns Hopkins, University of Missouri, University of Wisconsin and Yale, but the remaining medical faculties throughout the country are still undecided. The dilemma confronting them is more important than it seems at first sight.

The folly of allowing military service to cut off the supply of future doctors, even in time of war, was

amply demonstrated by the sad fate of the Nazi Medical Corps, and there can be no quarrel with the deferment of men already embarked on a medical career. Whether we are fated to live through a long cold war, another hot war or no war at all, they will be needed. It was presumably at this point in their thinking that National Headquarters issued Memorandum No. 7.

But thinking need not stop there. The question is not the deferment of medical students but the deferment of "premedical" students. Granted that medical training is long, will a college freshman who is eighteen months older for having done his military service be, for that reason, deterred from following the career for which he believes himself best fitted? And, more important, can an eighteen-year-old boy be counted on to evaluate maturely his motives for calling himself "premedical" and accepting draft deferment? Certainly a youthful desire to escape the draft would be an inadequate and unfortunate motivation for the support of a life-long career in medicine — a career, by the way, that will not and should not exclude the possibility and the duty of later military service.

The decision arrived at by the Harvard Faculty is surely foresighted and sound, and it is hoped that a similar clarity of thought and sincerity of purpose will guide the rest of the medical faculties in resolving the serious issue that Memorandum No. 7 has placed before them.

MASSACHUSETTS MEDICAL SOCIETY

TREASURER'S REPORT COVERING REFUND DISTRIBUTION

The Treasurer of the Massachusetts Medical Society makes the following report regarding the refund to the district societies for 1949.

The Council voted to distribute the sum of \$8000.00 to district societies. The total number of payments of annual dues received by the Treasurer by March 1, to be counted for the refund, was 4647. Therefore, the refund to the district societies for each paid fellow is \$1.72.

The following table gives the number of payments, as of March 1, and the refund to each district as of March 9.

DISTRICT	NUMBER REPORTED PAID	REFUND
Barnstable	44	\$76.07
Berkshire	126	217.12
Bristol North	60	103.59
Bristol South	197	339.24
Essex North	181	311.72
Essex South	254	437.28
Franklin	45	77.79
Hampden	298	512.96
Hampshire	72	124.23
Middlesex East	132	227.44
Middlesex North	125	215.40
Middlesex South	936	1,610.32
Norfolk	870	1,496.80
Norfolk South	140	241.20
Plymouth	140	241.20
Suffolk	577	992.84
Worcester	362	623.04
Worcester North	88	151.76
	4,647	\$8,000.00

In 1948, for comparison, the total number of payments for the refund was 4541.

DEATH

MEACHEN — John W Meachen, M.D., of Boston, died on February 24. He was in his fifty-seventh year.

Dr Meachen received his degree from Harvard Medical School in 1922. He was formerly a member of the staffs of the Massachusetts General Hospital, Cambridge Hospital, Free Hospital for Women in Brookline, Henry Heywood Memorial Hospital in Gardner, New England Hospital for Women and Children and Weymouth Hospital. He was a member of the New England Roentgen Ray Society and a fellow of the American Medical Association.

His widow, a son, a daughter, his mother, two brothers and two sisters survive.

NEW HAMPSHIRE MEDICAL SOCIETY

DEATHS

DOLLOFF — Albert S Dolloff, M.D., formerly of New Hampshire, died on March 6. He was in his eighty-seventh year.

Dr Dolloff received his degree from Dartmouth Medical School in 1891. He was an affiliate fellow of the American Medical Association.

A son survives.

HART — Malcolm A H Hart, M.D., of Milton, died on January 24. He was in his eighty-eighth year.

Dr Hart received his degree from New York University Medical College in 1888.

Two sons, three grandchildren and three great-grandchildren survive.

Lecture Hall, 9-10 a m

MEDICAL CONFERENCE PROGRAM

Tuesday, April 5 — Journal Review

Friday, April 8 — Some Further Notes on Auscultations of the Heart. Dr Samuel Levine

Wednesday, April 13 — Pediatric Clinicopathological Conference. Drs James M. Baty and H. E. MacMahon

Friday, April 15 — Fat in Parenteral Nutrition. Dr Fredrick J. Stare

Tuesday, April 19 — Holiday — No conference

Friday, April 22 — Some Observations on the Metabolic Requirements in Surgical Patients. Dr Francis D. Moore

Tuesday, April 26 — Newer Hematologic Methods for Studying the Blood Cells. Dr Marvin Bloom

Friday, April 29 — To be announced

From 9 to 10 a m on Wednesday (except the second Wednesday), Thursday and Saturday mornings, clinics will be given by members of the hospital staff. Medical rounds are conducted each weekday except Saturday by members of the hospital staff from 12 to 1 p m. On the first and fourth Fridays of the month, April 1 and 22, Therapeutic Conferences will be held with round-table discussion from 2 to 4 p m, with Dr Robert P. McCombs as moderator. On the first and fourth Fridays, April 1 and 22, Dr Merrill Sosman will conduct X-Ray Conferences from 4 to 6 p m.

On Saturday mornings from 9 to 10 a m Surgical Clinics are conducted by Dr C. Stuart Welch.

All exercises are open to the medical profession.

NEW ENGLAND HOSPITAL FOR
WOMEN AND CHILDREN

The monthly clinical conference and meeting of the staff of the New England Hospital for Women and Children will be held on Thursday, April 7, at 7 15 p m, in the classroom of the Nurses' Residence, under the chairmanship of Dr Ann P. D. Manton. Dr Lorne E. Hackworth will speak on the subject "Congenital Intestinal Abnormalities in the Newborn."

HARVARD MEDICAL SOCIETY

A meeting of the Harvard Medical Society will be held in the Lower Out-Patient Department Amphitheater, Massachusetts General Hospital, on Tuesday, April 12, at 8 p m.

PROGRAM

Anatomy and Physiology of Splanchnic Pathways from the Viscera. Dr James C. White

Anatomy and Physiology of Pain Pathways in the Brain Stem and Spinal Cord. Dr William H. Sweet.

A subsequent meeting will be held on May 10.

NEW ENGLAND DERMATOLOGICAL SOCIETY

The regular annual meeting of the New England Dermatological Society will be held in the Skin Out-Patient Department of the Boston City Hospital on Wednesday, April 20, at 2 p m.

These meetings are open only to members and invited guests.

LONG ISLAND COLLEGE ALUMNI ASSOCIATION

The sixty-ninth annual dinner of the Alumni Association of the Long Island College of Medicine will be held at the Columbus Club, 1 Prospect Park West, Brooklyn, New York, on April 30, 1949, at 7 p m. The principal speaker will be Dr Jean Curran, president of the Long Island College of Medicine.

AMERICAN SOCIETY OF
MEDICAL TECHNOLOGISTS

The seventeenth annual convention of the American Society of Medical Technologists will be held at the Hotel Roanoke, Roanoke, Virginia, from June 20 to 23. Further information may be obtained from Miss Ida L. Reilly, MIT (ASCP), Roanoke Hospital Association, Roanoke, Virginia, the convention chairman.

VETERANS ADMINISTRATION RESIDENCY
TRAINING IN NEUROPSYCHIATRY

A limited number of openings are available for July 1, 1949, appointment to the Veterans Administration residency-training program in neuropsychiatry. This program is under the jurisdiction of the deans of the Boston medical schools (Harvard, Tufts and Boston University). Training in this program, which may be from one to three years, is given at the following institutions:

Cushing Veterans Administration Hospital,
Frammingham, Massachusetts

Bedford Veterans Administration Hospital,
Bedford, Massachusetts

The Mental Hygiene Clinic of Boston,
Regional Office of Veterans Administration

Boston, Massachusetts

West Roxbury Veterans Administration Hospital,
West Roxbury, Massachusetts

White River Junction Veterans Administration Hospital,
White River Junction, Vermont

Emphasis in the entire program is on psychiatry with dynamic orientation and includes closed-ward, open-ward and outpatient care, child psychiatry and neurology.

All stations are within commuting distance of the Boston Psychoanalytic Institute, in the event that applicants have been accepted for analytic training.

Further information may be obtained from Dr J. L. Hoffman, chief, Professional Services, Bedford Veterans Administration Hospital, Bedford, Massachusetts, or from Dr Wilfred Bloomberg, chief, Neuropsychiatric Service, Cushing Veterans Administration Hospital, Frammingham, Massachusetts.

MEDICAL MISSION TO GREECE AND ITALY

CHESTER M. JONES, M.D.*

BOSTON

DURING the spring of 1948, medical missions were sent out under the auspices of the Unitarian Service Committee to various university centers, one to Greece and Italy, one to Poland and Finland, one to Germany, and one to Colombia. The present report deals briefly with experiences of the Greek-Italian Mission, which operated under the chairmanship of Dr. Paul D. White. Like that of previous missions organized and sponsored by the Unitarian Service Committee, its purpose was to meet important medical groups at a university level in centers that had been separated by the war from sources of new information over a period of years. By means of direct contact with heads of departments and with leading practitioners, it was possible to accomplish this and, what seemed of equal importance, to re-establish professional relations that had been broken since 1938. The sponsorship of this particular mission was divided between the Unitarian Service Committee and American Aid to Greece (AMAG), the agency through which the United States is providing material aid and professional advice to that unhappy country.

To give a representative background to professional opinion, the group was comprised of men from five American Universities and one Canadian institution and represented departments of physiology, bacteriology, pharmacology, internal medicine, general surgery, neurologic surgery, oral surgery, anesthesiology and dental research. Official invitations had been received from the universities of Athens and Salonika in Greece and from the faculties of Rome, Florence, Bologna, Turin and Milan in Italy. The procedure in each center was the same — that is, immediate and direct contact with the medical faculty, a series of planned formal lectures with the aid of medical interpreters and, much more important, a series of informal meetings as well as ward rounds and visits to various hospital centers in the areas concerned. By such an approach it was possible to establish a friendly relation with key individuals and to see at close range the existing problems, not only those that affected

the teaching of medicine and the care of the sick but also the political and social ones. A great deal of information was made available through embassy officials, governmental agencies and casual conversations with medical students and civilians who were encountered in the various cities.

The situation in Greece during the April and May of our visit was extremely critical, inasmuch as the Greek Government was attempting to wage an internal war successfully and at the same time to reconstruct a country ravaged and depleted by Italian and German occupation and subsequent guerrilla activities. At the time of our arrival a certain amount of stability was being obtained through the help of AMAG, which provided both military aid and advice and the actual distribution of relief to refugees and to communities in dire need of reconstruction and reorganization. From the first it was apparent that military necessities were uppermost, with the result that the needs of education and medical care were forced into a position of secondary importance. Added to this was the evident and appalling overcrowding in the schools, both in Athens and in Salonika. Although this applied to all departments of the universities, it was especially true in the medical schools, where there were approximately 4000 registered students in Athens and 2000 in Salonika. This student load imposed almost impossible difficulties in the way of adequate instruction, which at best had to be largely didactic. Besides the difficulty of excessive numbers, instruction was hampered by two factors: the relatively small number of experienced senior men, and the almost complete dearth of properly trained younger faculty members. The latter was due in part to actual losses during the war and in part to the fact that during the war years no planned, thorough training program could be maintained to provide for a sufficient number of younger men, because of the immediate and pressing necessities of care for the sick and indigent. As a result of all these circumstances, in addition to the fact that there had been little or no access to sources of current medical progress, Greek medicine was just beginning to emerge from a static phase of some years' standing.

(Notices concluded on page xiii)

interest was maintained and a very friendly atmosphere existed in centers where it was entertained.

An unforgettable by-product of the Greek Mission was a visit to the ecclesiastic community on Mt Athos, made possible by special permission from the Greek Government and from the ecclesiastic authorities. This community is completely isolated from the present-day world by its own, centuries-old traditions and practices. It is composed of some twenty monasteries situated on the tip of the Mt Athos peninsula. The Mission had an opportunity to see several of these monasteries, an experience of extraordinary interest because of the rich tradition of church lore and custom that went back to the period of Byzantine influence. The costumes and treasures were fascinating. Many of the monks were examined at their own request. With rare exception, these men who live an almost medieval type of life were in good physical health. Infectious disease seemed to be nonexistent, except for mild forms of endemic dysentery. Because of their extreme seclusion, psychosomatic disorders were not uncommon, but degenerative disease appeared to be at a minimum. A large number of monks were well into the eighth and ninth decades. The psychologic difficulties were noted more often in the younger monks, many of whom were obviously insecure and rather frustrated.

The effects of guerilla warfare were everywhere evident. Athens and Salonika were crowded with refugees, and really adequate nutrition for the average person was a critical problem. Sufficient food was available only for those of means, there were still evidences of wealth among a few. In Salonika, particularly, the fruits of guerilla warfare were seen at close hand. Troops and gendarmerie filled the city, and the military hospital was overflowing with recent casualties, most of which were being taken care of fairly efficiently although at times measures had to be improvised, owing to the lack of equipment and supplies. Civilian casualties were also numerous and presented a depressing sight. Periodically, guerilla forces raided outlying villages that were totally undefended and killed or maimed old men, women and children indiscriminately for no other purpose than to create terror and force evacuation of farms and villages. Survivors of these raids were occupying hospital beds and were kindly treated although under very difficult circumstances. They were frequently found side by side with unwounded children who were being temporarily housed in the hospital because of lack of other facilities. In these unfortunates the effects of starvation were obvious and distressing.

One special aspect of medical education in Greece is worthy of comment — that is, the plight of the medical student. Mention has already been made of the gross overcrowding of the schools. Following central and often western European tradition, there is no screening of medical students prior to matric-

ulation. This is one of the causes of the tremendous crowding, and as a result medical students are ill equipped for study and work. Housing conditions are poor and insufficient, textbooks and periodicals are noticeable by their absence. Student libraries exist but are totally inadequate to supply the student needs. Reading is almost entirely limited to textbooks, which are usually out of date, and consequently the difficulties imposed by restricted laboratory and hospital facilities and by the didactic method of teaching are enhanced by the impossibility of access to sources of modern medical information. A great number of the students are extremely poor, and living is almost at a subsistence level. Faculty interest in students is traditionally a distant one, although a few outstanding exceptions were encountered, where members of the faculty and their wives were trying to do everything within their power to make the lot of the student a happier one. Resident and research facilities such as are known in this country are nonexistent.

Finally, tribute should be paid to individual members of the AMAG group who were particularly interested in public health and education. Among numerous other activities, this group has been instrumental in the distribution of much-needed supplies and has gradually increased medical facilities although these are still far below optimal levels.

* * *

In Italy the work of the Mission proceeded along lines similar to those followed in Greece but at a much more rapid rate. The universities at Rome, Turin, Milan, Bologna and Florence were visited in turn. In addition to a series of formal lectures before faculties and students, interesting personal contacts were made between individual members of the Mission and their corresponding faculty members in the various cities. The transition from Greece to Italy showed sharp contrast despite the fact that Italy is far from restored to a normal level of political or social activity. Here too laboratories often evidenced the lack of many essential supplies and diagnostic equipment, medicines were absent or difficult to obtain. In the universities visited, the level of faculty activity was less restricted, and modern methods were being utilized in many instances very effectively and intelligently. Research was being carried on in individual units although under the ever-present limitations imposed by insufficient personnel and equipment. Scientific curiosity was keen in many quarters. Experienced clinical skill and awareness of the recent advances in medicine and surgery were obvious in the departments that were visited. The Forlanini Institute of Rome, for example, was a magnificent structure for the care of tuberculosis. It was thoroughly up-to-date and well equipped with ample provision for animal work and for modern therapeutic measures incident to the treatment of tuberculous

Because of depletion of scientific supplies and lack of funds for replacement, university, hospital and laboratory shelves were empty, or at best held very meager and ill balanced equipment of all sorts. Many important drugs were lacking, facilities for nursing and dietary care existed at only basic levels, and the hospital beds were filled to overflowing because of the great influx of civilian and military casualties.

The Greek medical situation has been colored of necessity by various developments in the country's history and tradition. This applies not only to the present critical situation but also to previous political, social and economic factors dating back at least to the beginning of the present Greek nation with its changing course under kings, republics and dictators. Economically poor, politically unstable and rarely organized from the point of view of efficient government, Greece has not had the opportunity to put on a firm basis sound medical traditions such as have obtained in other continental centers — in Vienna for example, where a greater degree of stability over a longer period has made it possible to establish great academic customs and advantages. The universities of both Athens and Salonika are governmental bodies, financially largely dependent on governmental grants (at present absent or completely insufficient). Appointments to the staff are in a sense political posts. Paralleling the changes in the Government, in Athens particularly, changes in faculty personnel are frequent, valuable men at times being replaced by others less capable but politically affiliated. This practice, not of course limited to Greece or even to Europe, represents a definite hazard to academic effectiveness since it leads to uncertainty of tenure of office and hence to inability to plan constructive departmental budgets, nor is the state of mind produced by such insecurity conducive to forward thinking even were other circumstances ideal.

Instruction in the medical schools, as noted above, was largely didactic, owing to the size of the classes. The clinical professors in many institutions were able, experienced physicians and surgeons, whose training reflected the teachings of the French, German and Austrian schools. Unfortunately, by tradition as well as by necessity of actual events, interest in and profound knowledge of the best in modern physiology and in the fundamental sciences was distinctly limited, although here again certain individuals stood out as men of great experience and learning. For the most part, however, teaching of the fundamental sciences was far behind what is currently demanded by modern medical concepts, and this was reflected in the therapeutic approach to disease, treatment being based chiefly on tradition and empiric knowledge rather than on physiologic and pharmacologic advances of recent years. The newer aspects of anesthesia were unknown, and consequently

present-day transthoracic surgery with all its implications was not possible. Newer drugs, such as penicillin and streptomycin, were available only in limited quantities. Furthermore, completely inadequate housing and feeding facilities rendered it impossible to care for the tremendous overload of infectious disease. Tuberculosis posed a menacing problem of great magnitude with no immediate hope of isolation of open cases or of proper therapy, although there were many physicians who were entirely capable of treating this disease under normal circumstances. To other difficulties there was added a certain amount of fatalistic apathy. This attitude, not limited to the medical profession, is the inevitable outcome of the Balkan wars and the two world wars that have harried Greece for many decades — to say nothing of the existing "civil war," which is essentially a struggle between the communistic elements, trained and supplied by outside sources, and the present rather inefficient Government. Uncertainty was in the air, particularly when the Mission arrived in Greece, although it was of extreme interest to note an ever-increasing spirit of optimism and hope subsequent to the improving military situation under American guidance and aid.

In contrast to the obvious difficulties and at times somewhat deplorable aspects of Greek medicine, certain achievements and certain bright spots stand out brilliantly. Gastric surgery in Athens was exceptionally well done. Subtotal gastrectomy was performed with a high degree of technical skill and low mortality, and experience in this particular operative procedure was great, inasmuch as the incidence of ulcer in the community, as reflected in the hospital population, was high. Echinococcal disease was extremely common, owing to the animal carriers that were completely uncontrolled by any sanitary measures, and as a result surgery of echinococcal cyst was also advanced and skillfully performed. Gynecology and obstetrics were at a high level of performance, at least in university centers, because of the outstanding work of the dean of the Athens Medical School. From the public-health point of view, the widespread and continuous campaign against malaria had borne fruit to the extent that active cases of malaria in Greece have been reduced to a few thousand instead of several million. DDT spraying by air over malarial areas has been most effective, and was the one activity that was not interfered with by guerilla groups. In spite of woefully inadequate supplies of streptomycin, treatment of tuberculous meningitis had been carried out with more or less immediate success in a small number of cases. Interest in newer methods of diagnosis and treatment was keen although frequently it was impossible for the local profession to act on information because of lack of facilities. During the entire stay of the Mission in Greece, a genuine

GASTRIC SUCTION A PROPOSED ADDITIONAL TECHNIC FOR THE PREVENTION OF ASPHYXIA IN INFANTS DELIVERED BY CESAREAN SECTION

A Preliminary Report

SYDNEY S. GELLIS, M.D.,† PRISCILLA WHITE, M.D.,‡ AND WILLIAM PFEFFER, M.D.§

BOSTON

IN THE course of a study involving approximately 500 infants born to diabetic mothers,¹ it became evident that respiratory difficulty, consisting of increased respiratory rate, cyanosis and retraction of the soft parts of the chest, was the most consistent abnormal finding in the neonatal course of these infants. These signs were frequently present at birth but also appeared several hours after birth and could not be correlated with hypoglycemia, cerebral injury or atelectasis, or with the cardiac hypertrophy that Miller² has found in such infants. The great majority of these infants had been delivered by cesarean section, it is well known that the incidence of respiratory difficulty and the mortality rate are higher in infants born by section than in those delivered through the pelvis. It therefore appeared possible that the mode of delivery was in part responsible for the abnormal respiratory signs noted in the infants of diabetic mothers. Delivery by cesarean section increases the likelihood of aspiration of amniotic fluid, and such aspiration seemed a likely explanation for the obstructive respiratory signs present immediately after birth. The aspiration of amniotic fluid during birth did not, however, appear to be an entirely satisfactory explanation for the sudden development of respiratory difficulty several hours after birth. It occurred to us that an excessive amount of amniotic fluid might be ingested at delivery and subsequently be regurgitated and aspirated, thus accounting for the late onset of respiratory embarrassment.

To test this hypothesis two series of infants of diabetic mothers were studied. All mothers received spinal anesthesia without analgesia and were delivered by cesarean section in the thirty-eighth week of pregnancy by the same obstetrician (Dr. Raymond S. Titus). All infants were observed at birth by one of us (S.S.G.), and all initial gastric suction was performed by the same person. The infants were extracted as quickly as possible to minimize the opportunity for crying or gasping before extraction of the head. The clearing of the airway and the administration of oxygen were per-

formed in a uniform manner in all infants. Gastric suction was carried out within one or two minutes of birth by means of a No. 10 French rubber catheter passed through the oropharynx. A resuscitator supplied the negative pressure for suctioning. The catheter was passed slowly down the mouth into the esophagus, with constant suction applied and with slow, rotating movements of the catheter between the fingers. When the catheter reached the stomach, gentle pressure was applied

over the abdomen to facilitate the greatest yield of fluid. The catheter was withdrawn slowly, still with constant suction applied. Tracheal catheterization was not carried out in any of the patients. Oxygen was then administered for approximately one or two minutes, after which the stomach suction was performed two or three more times until fluid could no longer be obtained. The infants were placed in incubators with oxygen flowing constantly at the rate of 6 liters per minute. Suction of the nares, nasopharynx, mouth and oropharynx was carried out as often as appeared necessary. After initial gastric suction had been performed, this

disease. It possessed an anatomic museum that was amazing in its completeness and in the arrangement of its specimens. Similarly, the Museum of Medical History in the University of Rome was extraordinarily well planned and filled with invaluable medical incunabula and exhibits. Original research on malaria was outstanding. Recent and quite modern buildings were to be seen in many of the medical centers, and in some, equipment of the finest quality and most recent pattern was available. It was evident that high medical standards were more universal and more widespread in Italy than in Greece, probably because of the greater age and number of Italian universities with their cherished traditions of many centuries.

As in Greece, however, there were gaps in medical knowledge, medical equipment and medical procedures. The student overload was just as apparent, in Rome, for example, there were said to be nearly 6000 medical students in the University. With few exceptions similar overcrowding appeared to be the case throughout all the medical schools in Italy. In spite of many individual brilliant clinicians and professors, the teaching load was so great that it was impossible to provide adequate instruction except at a lecture level. Bedside teaching was being carried out but by comparison with American standards was poor as far as quality and quantity were concerned. Laboratory investigations were limited by the variation in equipment and supplies to be found in the different laboratories. As in Greece, it was evident that interest in the fundamental sciences, as far as instruction of medical students goes, left much to be desired. Training in biochemistry lagged far behind, and a real understanding of and interest in physiologic processes was frequently superficial rather than basic and profound. Modern concepts of the treatment of nutritional disturbances, particularly in relation to preoperative and postoperative care, were little understood and would have been difficult to carry out because of actual food shortages. Ancillary services such as social service and occupational therapy were rudimentary, accurate follow-up study of therapeutic measures was difficult and with few exceptions unobtainable.

In Italy, however, possibly because of a more stabilized political and social situation, medical

progress was being made, and a good deal of optimism was evident. Political uncertainties were still apparent, and the threat of great events that might again disturb forward progress in scientific and other realms was apprehended in all conversations. Even more than in Greece, interest and enthusiasm for American methods were evident, this was due at least in part to the fact that many of the ablest Italian physicians and surgeons were personally acquainted with the American trend of thought. In fact, throughout the European phase of the Mission, innumerable friendly contacts that had been interrupted by the war were re-established. As in Greece, the inequalities existing between the inner few and the remainder of the population were noticeable. A desire for American aid was frequently balanced by a lack of desire to depart from the *status quo* of those who were socially and economically in the more fortunate groups. This applied particularly to nonprofessional people encountered outside the medical centers. Almost everywhere an urgent wish was apparent, however, for American aid and co-operation. Again it should be mentioned, as in Greece, that vigorous anti-malaria measures have resulted in almost complete eradication of this disease in the peninsula, at least as compared to its previous prevalence. Preventive medicine and public-health measures as well as nutritional problems were talked about frankly but as yet are but inadequately met, particularly in the southern part of the country. Reconstruction is going on apace, and hope for steady forward progress was everywhere evident.

* * *

In short, the experience of the Mission to Greece and Italy was similar to that of the missions to Czechoslovakia and Austria of 1946 and 1947, in that it was possible to achieve a satisfactory approach to the leaders of the medical profession in a friendly scientific spirit, unbiased by political events or internal difficulties. These difficulties were only too obvious at times, but frank, earnest discussions were possible and mutual contributions were made that were of great value. Probably as important as anything else was the re-establishment of friendly professional relations between groups that had been cut off from normal scientific contacts for many years.

procedure was repeated by the nurse on duty every three hours for twelve hours. No attempt to reduce oxygen was made until the fourth day of life. Glucose feedings were started at thirty-six to forty-eight hours after birth, and a 2 per cent milk formula at seventy-two hours. All infants received their feedings in the incubator and were under constant observation by nurses with long experience in the care of infants of diabetic mothers. Daily physical examinations were performed by the same physician. Examination of the gastric

marized in Table 4. Finally, 5 infants of diabetic mothers delivered by low forceps, whose gastric contents were measured, are included in Table 5. Figures for gastric contents apply only to the material obtained within the first few minutes after delivery. Material obtained subsequently was not included.

contents revealed the presence of cornified epithelial cells, lanugo hair and shreds of blood and mucus.

In Table 1 are listed the birth weights of the infants, the total quantity of gastric contents and the positive findings, if any, noted during the early neonatal period. In Table 2 similar data for the control group of infants in whom gastric suction was not performed are recorded. Identical studies were conducted on infants of nondiabetic mothers delivered at term under spinal anesthesia by cesarean section because of disproportion. These infants were delivered by various obstetricians, the findings are summarized in Table 3. To compare the quantities of gastric contents of such infants with those of infants delivered by low forceps, an additional group was studied and is sum-

marized in Table 4. Finally, 5 infants of diabetic mothers delivered by low forceps, whose gastric contents were measured, are included in Table 5. Figures for gastric contents apply only to the material obtained within the first few minutes after delivery. Material obtained subsequently was not included.

The small number of patients studied, together with variables introduced by differences in birth weight, severity and duration of diabetes in the mother, ease and rapidity of delivery and so forth, makes a statistical comparison of the "diabetic" groups impossible. However, the clinical course of the two groups of infants differs considerably. Four infants in the group receiving gastric suction (Table 1) developed mild respiratory difficulties, in all 4, abnormal respiratory signs were present at birth. Of the 25 infants who did not receive suction (Table 2) 15 developed respiratory difficulties, 9 of these were normal at birth, and respiratory embarrassment subsequently appeared. The severity of respiratory embarrassment was much more marked in this group of infants. There were no deaths in either group, and all infants breathed spontaneously at birth. The gastric contents obtained in the group

respiratory difficulty. Of 25 infants in whom suction was not performed 15 developed respiratory difficulty, in 6 it was present at birth, but 9 of the fifteen showed a delayed onset of obstructive signs.

The average quantity of gastric contents in infants of diabetic mothers, all of whom were delivered by cesarean section was 20 cc. An average of 14 cc of fluid was obtained from the stomachs of infants of nondiabetic mothers delivered by cesarean section because of disproportion. Infants of nondiabetic mothers delivered by low forceps yielded an average of 2 cc.

In view of the marked difference in the neonatal course of infants who received gastric suction and of those who did not, it is proposed that gastric suction at birth be carried out in infants delivered by cesarean section, in addition to the procedures now commonly employed for the prevention of asphyxia. Whether or not gastric suction will affect the clinical course of infants of nondiabetic mothers delivered by cesarean section remains to be determined.

GYNECOMASTIA IN ASSOCIATION WITH CHRONIC ULCERATIVE COLITIS*

LAURENCE H. KYLE, M.D.†

WASHINGTON, D. C.

DURING recent months the problem of gynecomastia has received increasing attention, especially its association with impaired hepatic function^{1,2} and malnutrition.³⁻⁵ Among the complications of chronic ulcerative colitis, liver disease has most recently attracted attention.⁶⁻⁸ The following case report is that of a patient with chronic ulcerative colitis who showed both hepatic impairment and gynecomastia and whose clinical picture was of such a nature as to allow some speculation regarding the pathogenesis of the latter condition.

CASE REPORT

A 24-year-old man had been in excellent health until 1944. At that time he developed frequent, painful, urgent, bloody, often watery stools, together with loss of appetite, weight and strength. Examination in an Army general hospital revealed no significant abnormalities. After a period of intensive therapy with antibiotics, a high-vitamin diet

parenteral administration of liver and a number of anti-diarrhea compounds improvement took place, and the patient was discharged with a diagnosis of simple diarrhea. He remained well for about 6 months until, in April, 1945, the symptoms recurred. Further studies were performed, and a diagnosis of chronic ulcerative colitis was made after sigmoidoscopic examination. Mild symptoms continued throughout 1945. During the first 2 or 3 months of 1946 the patient was asymptomatic, but in April the original symptoms returned with full severity and continued throughout the summer with some amelioration in the early fall.

During November and December, 1946, together with recrudescence of marked gastrointestinal symptoms, there was a severe attack of polyarthritides. Throughout the early part of 1947 he continued to have severe diarrhea, and there was a steady loss of weight. In March glycosuria and hyperglycemia were first noted, small doses of insulin were given and after a time the glycosuria disappeared. The patient had never shown glycosuria previously, and the family history was entirely negative for diabetes.

In May, 1947, the intestinal symptoms had become so severe and loss of weight so profound, that ileostomy was performed. After this procedure there was marked improvement, with a return of appetite and a steady gain of weight.

The patient continued a very high vitamin B intake for some weeks after the operation, but then since he felt so well, he began to discontinue the use of extra vitamins until finally, in the latter part of the summer, he was taking no supplementary vitamins of any sort. Glycosuria reappeared, and large doses of insulin were necessary for control. Shortly

respiratory tract by the compressive action of the birth canal upon the chest of the infant¹⁴⁻¹⁷ and that such cleansing serves to remove much debris that would otherwise be aspirated with the first breath. Russ and Strong^{9, 18} have demonstrated this by their findings of increased amounts of material in the tracheas of infants delivered by cesarean section. The improvement in mortality rate and in the incidence of respiratory difficulty that they found after the use of routine tracheal catheterization attests to the practicality of their observations.

In infants delivered by cesarean section a syndrome of delayed respiratory difficulty of an obstructive nature has been repeatedly described with unusual uniformity^{9, 17, 18} a presumably normal infant, after cesarean section and routine newborn care, develops signs of respiratory distress minutes to hours after delivery. There may be mild or marked inspiratory retraction, with dyspnea, tachypnea and cyanosis. Restlessness, a weak, high-pitched cry and at times convulsions may be present. Oxygen therapy is efficacious at the start, but the signs tend to recur with increasing severity and decreasing response to oxygen, death may ultimately occur with cyanosis and respiratory obstruction.

The cause of this delayed respiratory distress may logically be sought in the process of birth itself. The observations of Russ and Strong^{9, 18} provide one explanation. The increased amount of fluid in the upper respiratory tract of these infants must necessarily be inhaled with the first breath unless removed by the physician. That this may not produce immediate symptoms is shown by the autopsy findings of Russ and Strong and by the observations of Farber and Sweet¹⁹. Aspirated material at first lies loosely distributed in the alveolar spaces, but each successive breath packs the debris against the alveolar walls, forming the "asphyxial membrane" composed of amniotic detritus, meconium, lanugo and vernix. Delayed respiratory obstruction is dependent on an increasingly impervious intra-alveolar membrane.

Potter and Rosenbaum¹⁷ have described an increase in the amount of cerebrospinal fluid producing external hydrocephalus at autopsy in this syndrome. Since asphyxia causes a transudate as an early manifestation²⁰ they believe that asphyxia is responsible for this syndrome, perhaps supported by the effect of the sudden pressure changes incident to abdominal delivery.

The present paper attempts to add another possible cause of delayed respiratory distress of the infant delivered by cesarean section—namely, ingestion with subsequent regurgitation and aspiration of amniotic fluid, blood and mucus. It is further suggested that routine gastric suction immediately after delivery by section should be performed in addition to the accepted measures

for neonatal care. Mention of the use of gastric suction is not made in any of the standard textbooks of obstetrics or pediatrics. A review of the literature over the past thirty years, however, reveals that Slawik,²¹ in 1925, recommended gastric lavage within the first two hours of life whenever asphyxia was present or the amniotic fluid appeared contaminated. He proposed thereby to prevent absorption of bacteria through the gastrointestinal mucosa, with consequent generalized sepsis, and to prevent aspiration of the material into the lungs. Although he reported that gastric suction was without harmful effects, he failed to advance convincing evidence of the validity of his proposal. The literature presents few figures on gastric contents of normal newborn infants with which to compare our findings. Only fifteen observations are recorded within one hour of birth^{22, 23}, the average content is 4.9 cc, with a range of 0.5 to 10.0 cc. If observations in the first twenty-four hours of life are included, 119 cases are available^{22, 24}, here the range is 0.5 to 12 cc, with an average of 3.7 cc. The average anatomic capacity of the newborn stomach is given as approximately 30 to 35 cc²⁵⁻²⁷. Although our series is small, it is evident that the gastric content of infants delivered by cesarean section is greater than that of infants delivered through the pelvis and, in some cases, approaches the maximum distensibility or anatomic capacity of the stomach. Whether or not the greater volume of gastric contents in infants of diabetic mothers is related to hydramnios, which occurs frequently in the pregnant diabetic patient, remains to be investigated.

To determine the value of gastric suction in the neonatal care of infants delivered by cesarean section a much larger group of normal infants together with controls will be required, the present study is subject to criticism because of the large number of infants of diabetic mothers.

SUMMARY

In an unpublished review of the neonatal course of the infants of diabetic mothers the outstanding abnormal signs consisted of cyanosis, dyspnea, tachypnea and retraction of the soft parts of the chest. These signs occurred immediately at birth or within several hours of birth. The majority of the infants were delivered by cesarean section, such signs not infrequently complicate the course of infants of nondiabetic mothers delivered by section. On the supposition that delayed respiratory signs of an obstructive nature might be due to the ingestion of large amounts of amniotic fluid followed by regurgitation and aspiration, a study was conducted on infants of diabetic mothers delivered by section to determine the effect of gastric suction on the frequency of these signs.

Of 25 infants receiving gastric suction at birth, 4 showed respiratory embarrassment that was present at birth, and none developed delayed

gynecomastia has never been definitely established. It is a basic premise that administration of estrogens will cause development of the male breast. In addition, there is considerable laboratory and clinical evidence that estrogens are not normally inactivated when hepatic function is impaired. Consequently, one feels quite secure in holding to the theory that gynecomastia in liver disease results from an excessive amount of circulating estrogen. Other features of cirrhosis attributable to an excessive amount of circulating estrogen are spider angiomas, testicular atrophy, "liver palms," decreased growth of axillary hair, impotence and

151 patients with colitis and noted in all marked hypoalbuminemia that was strikingly refractory to treatment. Johnson⁷ reviewed 25 cases of chronic ulcerative colitis and found that a palpable liver had been noted in 5. Two of these patients were studied and proved to have hepatic insufficiency. After reviewing the possible causes of the insufficiency he concluded that a combination of the factors of poor nutrition and absorption of toxic substances from a diseased bowel could be operative.

During World War II the incarceration of large numbers of prisoners by the Japanese provided an optimal environment for the development of malnutrition on a mass scale. In addition to other developments in prisoners kept for long periods on semi-starvation diets, gynecomastia was frequently noted. Malnutrition in its far-reaching effects on the human organism provides a number of possible mechanisms for the development of gynecomastia.

loss of libido in the male, and change of menstrual pattern in the female. The possibility that testicular atrophy in patients suffering from cirrhosis of the liver develops on a nutritional basis and the well documented association of other types of testicular atrophy with gynecomastia lend some support to the idea that gynecomastia in liver disease may be secondary to testicular changes. However, experimental production of testicular atrophy by administration of estrogens, especially in the presence of hepatic disease, validates the concept that both this complication and that of mammary enlargement may be due to insufficient inactivation of estrogens.¹⁰ The liver disease usually accompanied by gynecomastia is cirrhosis. Edmondson¹¹ noted this fact and asked why a similar development could not take place in less chronic liver disease. Since then Klatzkin² has reported 2 cases of gynecomastia in patients with infectious hepatitis.

It is of interest that the patient described above showed histologic evidence of hepatic disease. Considerable attention has recently been paid to the frequency of hepatic disease in patients suffering from chronic ulcerative colitis. Tumen, Monaghan and Jobb⁶ reported 5 cases with cirrhosis among

Undernourishment may cause hypofunction of the pituitary body, with consequent secondary impairment of activity of such target endocrine organs as the adrenal glands and gonads.

Testicular atrophy may result from deficiencies of specific nutrients necessary for preservation of testicular structure and function.

Vitamin deficiency, especially lack of components of the B complex, could well be the important factor. Of interest in this regard is the experimental work of Biskind,^{12, 13} who found that whereas inactivation of estrogen requires the presence of adequate amounts of vitamin B₆, androgen inactivation does not. Consequently changes in the androgen-estrogen ratio could readily occur in patients deprived of these vitamins.

Hepatic impairment of a primary type or aggravation of latent mild liver disease with consequent inactivation of estrogens as outlined above must be considered as a possibility in all poorly nourished patients.

One of the most interesting features of the gynecomastia seen in malnourished prisoners of war was either primary development or increase in severity when the prisoners were allowed a more liberal diet. This observation, made first by Klatzkin² and later elaborated upon by Jacobs,⁵ may have considerable bearing on the pathogenesis of certain types of gynecomastia and is directly applicable to the case reported above. Jacobs has suggested that during the period of starvation lack of normal amounts of hormone-building material results in deficient production of the steroid hormones. This deficiency is rapidly overcome upon resumption of a more adequate diet. The hepatic impairment resulting from prolonged malnutrition is slower of recovery, with consequent temporary lack of inactivation of the newly formed estrogens.

thereafter the patient first noticed a tender mass in the left breast. This mass increased in size, and soon thereafter a similar mass appeared in the other breast. At about the time that the breast changes were most severe, the patient underwent colectomy. At this time both breasts showed firm, well demarcated masses measuring in diameter 5 cm on the right and 3.5 cm on the left. They were freely movable, and the one on the right was tender. There was a moderate amount of palmar erythema, but no cutaneous telangiectasias were observed. Both testes were present in the scrotum and were of normal size and consistence. The patient could recall no previous occurrence of mammary tenderness or enlargement.

Liver biopsy taken at the time of the colectomy showed early parenchymatous degeneration, with slight fibrosis. The postoperative course was very stormy. The diabetes increased greatly in severity, and the patient became mildly jaundiced. However, during the next few weeks there was gradual improvement on a therapeutic regimen that included high-vitamin intake, blood transfusions, antibiotics and insulin. At this time the gynecomastia gradually diminished. Shortly after discharge from the hospital he continued to improve, and the glycosuria subsided to a point where only

ulcerative colitis could well have been associated with impaired hepatic function. Of further interest is the fact that there was marked increase in the severity of the diabetes during the period when the gynecomastia appeared. Some correlation may be seen between the increase in severity of the diabetes and the cessation of adequate intake of vitamin B. However, the increased insulin requirement can also be correlated with increased caloric intake.

Although breast enlargement in the male is occasionally due to a neoplasm, by far the more common causes are either excessive deposition of fat (pseudogynecomastia) or development of glandular tissue similar to that of the female breast (true gynecomastia). These conditions are frequently confused. Gynecomastia may be divided into three

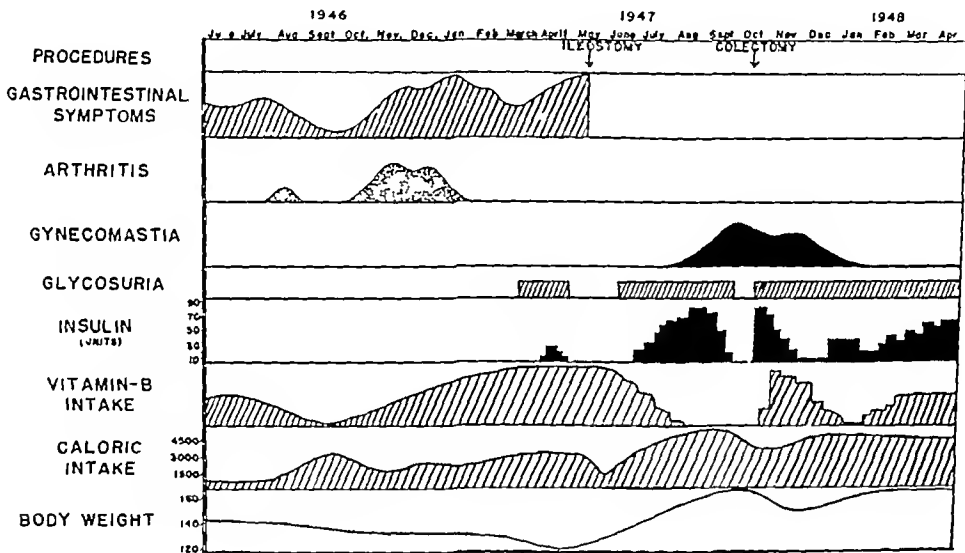

FIGURE 1 Clinical Course

small doses of insulin were required. At this time a decrease of the vitamin intake was again followed by aggravation of the diabetes but without any further changes in the breasts, which then showed barely palpable masses. Again, after a more adequate intake of vitamins, there was improvement of the diabetes. This improvement, however, was only temporary, and since that time the patient has continued to require large doses of insulin even though on a very adequate vitamin intake. The salient features of the clinical course are shown in Figure 1.

DISCUSSION

Several points are worthy of emphasis. Although there was evidence of hepatic disease the gynecomastia did not develop while the liver disease was presumably most severe. Rather, the mammary enlargement appeared when the patient was eating heavily, gaining weight and in much improved general condition, but at a time when he was beginning to neglect his vitamin intake.

The development of diabetes without the usual familial background and during the height of the

forms that appearing in boys at the time of puberty, referred to by Jung⁹ as the subareolar node, idiopathic or "nonhormonal," a type described much more frequently in the surgical than in the medical literature and less often described since the advent of more intensive metabolic studies, and true or "hormonal" gynecomastia. The last type is seen in numerous conditions, the majority of which allow a fairly reasonable hypothesis regarding the pathogenesis of the mammary enlargement. The more important causes of true gynecomastia are summarized in Table 1. Only those types that have a possible application to the case reported here are discussed in any detail.

Gynecomastia has been noted for many years as a not uncommon feature of hepatic cirrhosis. When testicular atrophy is also present, the combination is referred to as the Silvestri-Corda syndrome. The mechanism of the development of

gynecomastia has never been definitely established. It is a basic premise that administration of estrogens will cause development of the male breast. In addition, there is considerable laboratory and clinical evidence that estrogens are not normally inactivated when hepatic function is impaired. Consequently, one feels quite secure in holding to the theory that gynecomastia in liver disease results from an excessive amount of circulating estrogen. Other features of cirrhosis attributable to an excessive amount of circulating estrogen are spider angiomas, testicular atrophy, "liver palms," decreased growth of axillary hair, impotence and

151 patients with colitis and noted in all marked hypoalbuminemia that was strikingly refractory to treatment. Johnson⁷ reviewed 25 cases of chronic ulcerative colitis and found that a palpable liver had been noted in 5. Two of these patients were studied and proved to have hepatic insufficiency. After reviewing the possible causes of the insufficiency he concluded that a combination of the factors of poor nutrition and absorption of toxic substances from a diseased bowel could be operative.

During World War II the incarceration of large numbers of prisoners by the Japanese provided an optimal environment for the development of malnutrition on a mass scale. In addition to other developments in prisoners kept for long periods on semi-starvation diets, gynecomastia was frequently noted. Malnutrition in its far-reaching effects on the human organism provides a number of possible mechanisms for the development of gynecomastia.

loss of libido in the male, and change of menstrual pattern in the female. The possibility that testicular atrophy in patients suffering from cirrhosis of the liver develops on a nutritional basis and the well documented association of other types of testicular atrophy with gynecomastia lend some support to the idea that gynecomastia in liver disease may be secondary to testicular changes. However, experimental production of testicular atrophy by administration of estrogens, especially in the presence of hepatic disease, validates the concept that both this complication and that of mammary enlargement may be due to insufficient inactivation of estrogens.¹⁰ The liver disease usually accompanied by gynecomastia is cirrhosis. Edmondson¹¹ noted this fact and asked why a similar development could not take place in less chronic liver disease. Since then Klatzkin² has reported 2 cases of gynecomastia in patients with infectious hepatitis.

It is of interest that the patient described above showed histologic evidence of hepatic disease. Considerable attention has recently been paid to the frequency of hepatic disease in patients suffering from chronic ulcerative colitis. Tumen, Monaghan and Jobb⁶ reported 5 cases with cirrhosis among

Undernourishment may cause hypofunction of the pituitary body, with consequent secondary impairment of activity of such target endocrine organs as the adrenal glands and gonads.

Testicular atrophy may result from deficiencies of specific nutrients necessary for preservation of testicular structure and function.

Vitamin deficiency, especially lack of components of the B complex, could well be the important factor. Of interest in this regard is the experimental work of Biskind,^{12, 13} who found that whereas inactivation of estrogen requires the presence of adequate amounts of vitamin B, androgen inactivation does not. Consequently changes in the androgen-estrogen ratio could readily occur in patients deprived of these vitamins.

Hepatic impairment of a primary type or aggravation of latent mild liver disease with consequent inactivation of estrogens as outlined above must be considered as a possibility in all poorly nourished patients.

One of the most interesting features of the gynecomastia seen in malnourished prisoners of war was either primary development or increase in severity when the prisoners were allowed a more liberal diet. This observation, made first by Klatzkin² and later elaborated upon by Jacobs,⁵ may have considerable bearing on the pathogenesis of certain types of gynecomastia and is directly applicable to the case reported above. Jacobs has suggested that during the period of starvation lack of normal amounts of hormone-building material results in deficient production of the steroid hormones. This deficiency is rapidly overcome upon resumption of a more adequate diet. The hepatic impairment resulting from prolonged malnutrition is slower of recovery, with consequent temporary lack of inactivation of the newly formed estrogens.

Resumption of adequate caloric intake after a prolonged period of starvation causes rapid depletion of vitamin stores and calls for a greatly increased vitamin intake. As Klatskin² has pointed out, unless the vitamins are supplied a period of relative vitamin deficiency may exist. Inasmuch as estrogen inactivation seems to depend on adequate amounts of vitamin B, whereas that of androgen does not, temporary reversal of the androgen-estrogen ratio may result. When one passes from a state of semistarvation to one of more adequate nutrition the obvious result should be an increase in tissue-affecting hormones secondary to increased pituitary activity or to a more adequate intake of hormone precursors. The theoretical possibility exists that

a number of patients similar to those of Klinefelter so far as tubular destruction was concerned except that Sertoli cells were present. These patients had no gynecomastia, and pituitary gonadotropins were present in normal amounts. McCullagh's¹⁷ report of development of gynecomastia in patients with hypogonadism treated with methyl testosterone lends further support to the probability that the male hormone is potentially able to cause glandular development in the male breast.

Even more confusing is the occurrence of gynecomastia following administration of desoxycorticosterone,^{18, 19} a synthetic steroid hormone that is a potent regulator of salt and water although it cannot ordinarily be implicated as affecting sexual structures. It is not inconceivable that some metabolic product common to several of the steroid hormones is the active mammogenic agent. A diagram expressing the possible mechanism of development of gynecomastia under conditions of hepatic insufficiency, vitamin deficiency and malnutrition is shown in Figure 2.

Why one person develops gynecomastia while another with an identical clinical pattern of disease shows no mammary-gland changes remains a problem. End-organ sensitivity or unresponsiveness can always be advanced as a simple but logical explanation. In this regard the observation of Jacobs⁵ is of interest. He noted that 15 per cent of patients with gynecomastia gave a history of having had previous breast enlargement at the time of puberty. It is possible that the breast in certain male patients is oversensitive and therefore responsive to amounts of circulating estrogen that in other persons are incapable of causing mammary stimulation.

Granting the fact that the pathogenesis of gynecomastia is complex, it remains a clinical entity of considerable diagnostic and therapeutic import. Its appearance should call for investigation aimed in the direction of ruling out all the possible etiologic factors presented in Table 1. When seen in any patient with hepatic disease or with a basic disease that may lead to malnutrition, gynecomastia should be accepted as an indication for more active therapy.

SUMMARY

A case that showed chronic ulcerative colitis, hepatic disease, diabetes and gynecomastia is presented. Various possibilities regarding the pathogenesis of the gynecomastia are discussed. Evidence is presented that the breast changes were probably due to a relative vitamin B deficiency.

Gynecomastia is discussed especially in respect to its appearance in hepatic disease, vitamin B deficiency and malnutrition. Emphasis is placed on the fact that a reasonable hypothesis can be advanced to explain the "hormonal" types of gynecomastia.

The importance of recognizing the presence of gynecomastia rests in its value, not only as a diag-

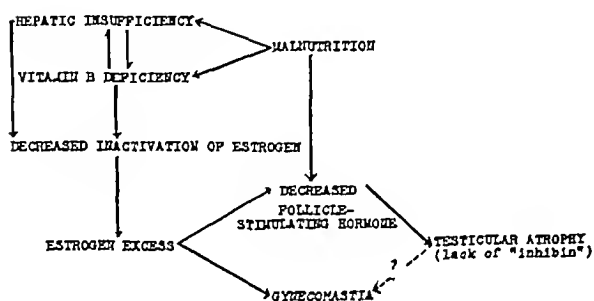

FIGURE 2 Possible Mechanisms in the Development of Gynecomastia

if the increased diet contains sufficient amounts of folic acid, mammogenic action of estrogens might be enhanced, for Hertz¹⁴ has demonstrated such synergism on the reproductive tract of chicks given both stilbestrol and folic acid.

Although the development of gynecomastia in such conditions as lead to malnutrition or impairment of hepatic function cannot be simply explained, the theory of estrogen excess appears quite credible. The appearance of gynecomastia in other conditions is much more difficult of explanation. One of the most interesting is the syndrome described by Klinefelter¹⁵ in which there is gynecomastia, atrophy of the testicular tubules, normal Leydig cells and a high titer of pituitary gonadotropins. The presence of increased gonadotropins, together with normal interstitial cells of the testes, speaks for deficiency of some testicular hormone other than androgen. Klinefelter believes that the deficiency is such as to prevent inhibition of androgenic activity and advances the presumption that androgen is, when uninhibited, a mammogenic hormone. The possibility that this inhibitory substance arises from the Sertoli cells is given credence by the observations of del Castillo¹⁶. He described

nostic clue in several conditions but also as an index of therapeutic control in patients with malnutrition or liver disease

EOSINOPHILIC GRANULOMA OF RIB*

Report of a Case Observed for Eight Years

AUSTIN R. GRANT, M.D.,† REGINALD K. HOUSE, M.D.,‡ AND WALTER B. CRANDELL, M.D.§

WHITE RIVER JUNCTION, VERMONT, AND HANOVER, NEW HAMPSHIRE

EOSINOPHILIC granuloma of bone has been regarded as a disease that occurs in children and young adults and locally has a rapidly progressive course. A recently observed case has directed attention to the fact that the disease occurs in the older age groups and that its course can extend over a period of years.

CASE REPORT

A 46-year-old laborer entered the hospital on November 14, 1939, for the repair of a left indirect inguinal hernia. A routine roentgenogram of the chest revealed an area of decreased density posteriorly in the medullary portion of the left tenth rib. The area was sharply defined and non-invasive in character, and associated with slight expansion and thinning of the cortex. A radiologic diagnosis of bone cyst was made (Fig. 1).

Examination of the blood disclosed a red-cell count of 4,690,000, with a hemoglobin of 90 per cent, and a white-cell count of 7250, with 64 per cent neutrophils, 34 per cent lymphocytes and 2 per cent monocytes. There were no symptoms or physical findings associated with this lesion. After a left inguinal herniorrhaphy and an uneventful post-operative course the patient was discharged.

During a readmission to the hospital for asthmatic bronchitis on November 30, 1946, roentgenologic examination of the chest again showed a symmetrical area of irregular bone density 1.5 cm by 2 cm, in the left tenth rib in the posterior axillary line. Examination of the blood revealed a white-cell count of 9000 with 60 per cent neutrophils, 34 per cent lymphocytes, 2 per cent monocytes, 3 per cent eosinophils and 1 per cent basophils. There were no complaints considered referable to the rib.

On February 23, 1948, the patient was again admitted to the hospital, this time with the chief complaint of sharp pain

over the left posterior portion of the lower chest of 1 year's duration, without radiation and without relation to exercise. Physical examination disclosed a small, firm, symmetrical

FIGURE 1 X-ray Film Taken on November 21, 1939, Showing a Cystic Lesion of the Left Tenth Rib

mass, tender to percussion, over the left tenth rib at the posterior axillary line. A roentgenogram of the chest showed no change in the mass (Fig. 2). Examination of the

EOSINOPHILIC GRANULOMA OF RIB*

Report of a Case Observed for Eight Years

AUSTIN R. GRANT, M.D.,† REGINALD K. HOUSE, M.D.,‡ AND WALTER B. CRANDELL, M.D.§

WHITE RIVER JUNCTION, VERMONT, AND HANOVER, NEW HAMPSHIRE

EOSINOPHILIC granuloma of bone has been regarded as a disease that occurs in children and young adults and locally has a rapidly progressive course. A recently observed case has directed attention to the fact that the disease occurs in the older age groups and that its course can extend over a period of years.

CASE REPORT

A 46-year-old laborer entered the hospital on November 14, 1939, for the repair of a left indirect inguinal hernia. A routine roentgenogram of the chest revealed an area of decreased density posteriorly in the medullary portion of the left tenth rib. The area was sharply defined and non-invasive in character, and associated with slight expansion and thinning of the cortex. A radiologic diagnosis of bone cyst was made (Fig 1).

Examination of the blood disclosed a red-cell count of 4,690,000, with a hemoglobin of 90 per cent, and a white-cell count of 7250, with 64 per cent neutrophils, 34 per cent lymphocytes and 2 per cent monocytes. There were no symptoms or physical findings associated with this lesion. After a left inguinal herniorrhaphy and an uneventful post-operative course the patient was discharged.

During a readmission to the hospital for asthmatic bronchitis on November 30, 1946, roentgenologic examination of the chest again showed a symmetrical area of irregular bone density, 1.5 cm by 2 cm, in the left tenth rib in the posterior axillary line. Examination of the blood revealed a white-cell count of 9000, with 60 per cent neutrophils, 34 per cent lymphocytes, 2 per cent monocytes, 3 per cent eosinophils and 1 per cent basophils. There were no complaints considered referable to the rib.

On February 23, 1948, the patient was again admitted to the hospital, this time with the chief complaint of sharp pain

over the left posterior portion of the lower chest of 1 year's duration, without radiation and without relation to exercise. Physical examination disclosed a small, firm, symmetrical

Resumption of adequate caloric intake after a prolonged period of starvation causes rapid depletion of vitamin stores and calls for a greatly increased vitamin intake. As Klatskin³ has pointed out, unless the vitamins are supplied a period of relative vitamin deficiency may exist. Inasmuch as estrogen inactivation seems to depend on adequate amounts of vitamin B, whereas that of androgen does not, temporary reversal of the androgen-estrogen ratio may result. When one passes from a state of semi-starvation to one of more adequate nutrition the obvious result should be an increase in tissue-affecting hormones secondary to increased pituitary activity or to a more adequate intake of hormone precursors. The theoretical possibility exists that

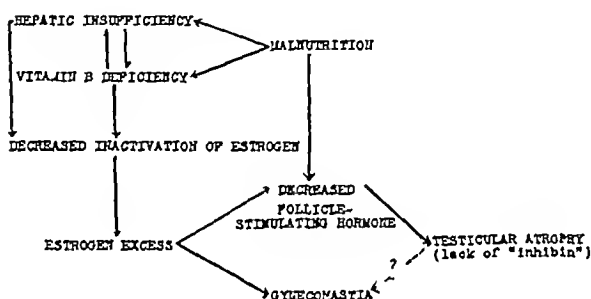

FIGURE 2 Possible Mechanisms in the Development of Gynecomastia

if the increased diet contains sufficient amounts of folic acid, mammogenic action of estrogens might be enhanced, for Hertz¹⁴ has demonstrated such synergism on the reproductive tract of chicks given both stilbestrol and folic acid.

Although the development of gynecomastia in such conditions as lead to malnutrition or impairment of hepatic function cannot be simply explained, the theory of estrogen excess appears quite credible. The appearance of gynecomastia in other conditions is much more difficult of explanation. One of the most interesting is the syndrome described by Klinefelter¹⁵ in which there is gynecomastia, atrophy of the testicular tubules, normal Leydig cells and a high titer of pituitary gonadotropins. The presence of increased gonadotropins, together with normal interstitial cells of the testes, speaks for deficiency of some testicular hormone other than androgen. Klinefelter believes that the deficiency is such as to prevent inhibition of androgenic activity and advances the presumption that androgen is, when uninhibited, a mammogenic hormone. The possibility that this inhibitory substance arises from the Sertoli cells is given credence by the observations of del Castillo¹⁶. He described

a number of patients similar to those of Klinefelter so far as tubular destruction was concerned except that Sertoli cells were present. These patients had no gynecomastia, and pituitary gonadotropins were present in normal amounts. McCullagh's¹⁷ report of development of gynecomastia in patients with hypogonadism treated with methyl testosterone lends further support to the probability that the male hormone is potentially able to cause glandular development in the male breast.

Even more confusing is the occurrence of gynecomastia following administration of desoxycorticosterone,^{18, 19} a synthetic steroid hormone that is a potent regulator of salt and water although it cannot ordinarily be implicated as affecting sexual structures. It is not inconceivable that some metabolic product common to several of the steroid hormones is the active mammogenic agent. A diagram expressing the possible mechanism of development of gynecomastia under conditions of hepatic insufficiency, vitamin deficiency and malnutrition is shown in Figure 2.

Why one person develops gynecomastia while another with an identical clinical pattern of disease shows no mammary-gland changes remains a problem. End-organ sensitivity or unresponsiveness can always be advanced as a simple but logical explanation. In this regard the observation of Jacobs⁵ is of interest. He noted that 15 per cent of patients with gynecomastia gave a history of having had previous breast enlargement at the time of puberty. It is possible that the breast in certain male patients is oversensitive and therefore responsive to amounts of circulating estrogen that in other persons are incapable of causing mammary stimulation.

Granting the fact that the pathogenesis of gynecomastia is complex, it remains a clinical entity of considerable diagnostic and therapeutic import. Its appearance should call for investigation aimed in the direction of ruling out all the possible etiologic factors presented in Table 1. When seen in any patient with hepatic disease or with a basic disease that may lead to malnutrition, gynecomastia should be accepted as an indication for more active therapy.

SUMMARY

A case that showed chronic ulcerative colitis, hepatic disease, diabetes and gynecomastia is presented. Various possibilities regarding the pathogenesis of the gynecomastia are discussed. Evidence is presented that the breast changes were probably due to a relative vitamin B deficiency.

Gynecomastia is discussed especially in respect to its appearance in hepatic disease, vitamin B deficiency and malnutrition. Emphasis is placed on the fact that a reasonable hypothesis can be advanced to explain the "hormonal" types of gynecomastia.

The importance of recognizing the presence of gynecomastia rests in its value, not only as a diag-

old when operated on, appears to be the oldest thus far recorded

It is of significant pathological interest that this eosinophilic granuloma was under roentgenologic observation over a period of nine years with no apparent change in size, shape or invasiveness. Yet Lichtenstein and Jaffe⁴ and Green and Farber¹ have observed that these destructive lesions develop rapidly, with tendencies toward bone destruction and spontaneous fractures. Throughout the period of observation, radiologic examination had revealed a circumscribed process, and at operation there was no gross evidence of extension to the periosteum. In confirmation, pathological study also disclosed that the local lesion was totally confined within a capsule of dense cortical bone.

SUMMARY

A case of eosinophilic granuloma of the rib is reported that presented two singular features: the

age of the patient, fifty-five years, when the lesion was diagnosed, and the nine-year period of observation without apparent physical change in the process.

MEDICAL PROGRESS

SURGERY OF THE AUTONOMIC NERVOUS SYSTEM

R. H. SMITHWICK, M.D.*

BOSTON

REPORTS dealing with various aspects of surgery of the autonomic nervous system are becoming more numerous each year. It is impossible to comment upon all of them. Consequently certain articles are referred to that have a bearing upon the topics selected for discussion in this review.

ANATOMY

For some time, particularly since Richter¹ devised a practical apparatus for studying the electrical resistance of the skin, surgeons have noted that after the removal of portions of the sympathetic chain and ganglions having to do with the sympathetic innervation of a particular area, evidence of residual pathways to that area still existed. This is particularly true of the anterior half of the thigh from the groin to the knee. In a recent discussion of this matter, Rav and Console² have pointed out that, even after bilateral excision of the sympathetic trunks from the inferior cervical to the fifth lumbar ganglions, residual sympathetic pathways, as judged by low skin-resistance levels, were present from the twelfth thoracic to the third lumbar dermatomes. They found that these pathways could be interrupted by spinal anesthesia, resection of

anterior roots, procaine block or division of the peripheral nerves, or by the administration of tetraethyl ammonium chloride. For some time, Cone³ has been resecting the anterior roots of the twelfth dorsal and first and second lumbar segments to denervate the thigh completely in his modification of thoracolumbar sympathectomy for hypertension. These observations are of interest because they indicate that sympathetic fibers can reach the sweat glands and, by inference, blood vessels, without passing through the paravertebral ganglionated sympathetic chains. It is difficult to believe that these fibers run without a synapse somewhere between the lateral horn and the end organ. The fact that these sympathetic impulses can be interrupted by tetraethyl ammonium chloride, which blocks transmission at the synapses in sympathetic ganglions, suggests that ganglionic tissue exists. It is apparent, however, that it is somewhere other than in the usual thoracic and lumbar ganglions. A possible explanation is contained in a recent article by Skoog,⁴ who found sympathetic ganglions in the communicating rami between the cervical and upper two thoracic ganglions and the spinal nerves. There was no regularity about their location. At times they were situated not far from the ganglionated chain, but at times they were very

*Professor of surgery, Boston University School of Medicine; surgeon-in-chief, Massachusetts Memorial Hospitals.

blood demonstrated a red-cell count of 4,240,000, with a hemoglobin of 13.6 gm, and a white-cell count of 7200, with 60 per cent neutrophils, 31 per cent lymphocytes, 6 per cent monocytes and 3 per cent eosinophils, the sedimentation rate was 23 mm in 1 hour.

On June 12, under a local field block of 1 per cent novocain, a subperiosteal partial resection of the left tenth rib was carried

At follow-up examination 6 months later, there was no pain in the left side of the chest. Physical examination disclosed a healed operative incision posteriorly over the course of the left tenth rib. Complete roentgenologic examination of the skeleton demonstrated no local recurrence of the original lesion but disclosed discrete areas of decreased density, consistent with the early bony lesions of eosinophilic granuloma, in the left parietal bone and in the spine of the first cervical vertebra. The patient was discharged to return in 3 months for further evaluation.

DISCUSSION

Analysis of approximately 46 cases reported to date in the literature has shown an age incidence ranging from eleven months¹ to thirty-nine years,² with the preponderance of cases in young children.

FIGURE 2 X-ray Film Taken on February 26, 1948, Showing the Same Cystic Lesion of the Left Tenth Rib

out. The lesion was a symmetrical, circumscribed mass without gross evidence of extension into the surrounding tissue.

The pathological report (S-48-120) was as follows:

The specimen consists of a 6.5-cm segment of rib. In the midportion there is a fusiform swelling measuring 2.5 by 2 by 1 cm. The external surface is smooth, firm and mottled gray-yellow. Section through this enlargement exhibits soft yellow-pink and brown tissue bordered by gray tissue of increased consistence. The entire lesion is surrounded by a layer of cortical bone, 2 to 3 mm in thickness.

On microscopical examination of all tissue blocks fixed in 10 per cent formalin, decalcified in 5 per cent nitric acid and stained with hematoxylin and eosin, the major part of each section consists of a vascular connective tissue containing solid sheets of macrophages with light-staining oval or lobulated nuclei and abundant cytoplasm. The cytoplasm exhibits abundant minute vacuoles. In a few areas there are focal accumulations of histiocytes and eosinophils. Encapsulating this lesion is a relatively avascular narrow border of connective tissue containing bone spicules adjacent to normal cortical bone (Fig. 3). The pathological diagnosis is eosinophilic granuloma.

Convalescence was uneventful, and the patient was discharged from the hospital 5 days after operation.

FIGURE 3 Central Portion of the Lesion
Note the abundant foamy-type macrophages with one focal accumulation of histiocytes and eosinophils (hematoxylin and eosin stain $\times 32$)

In 1944, Versiani et al.³ presented a case report of a fifty-year-old woman with an eosinophilic and xanthomatous granuloma of the femur associated with diabetes insipidus, which was finally classified as a variation of Hand-Schüller-Christian disease. Thus, our patient, who was forty-six years of age when the lesion was first noted and fifty-five years

urecholine Doryl appears to be less effective and is more toxic

After resection of the vagus nerves, the fasting free acid levels are decreased by a third or more, and the secretory responses to sham feeding and insulin hypoglycemia are abolished. Evidence concerning the effect of operation upon the chemical or gastric phase of gastric secretion is conflicting. Stein and Meyer²⁰ report a marked reduction in the secretory response to histamine, whereas Schoen and Griswold²¹ find no significant change and believe that the histamine effect is independent of the vagus innervation. Different methods for studying gastric secretion were used by these two sets of authors, the former employing continuous suction and the latter intermittent aspiration with phenol red as an indicator to enable them to estimate emptying and secretory rates. They believed that this technique was more accurate than continuous suction, and the differences observed might possibly be explained on this basis. On the other hand, most observers use continuous suction, and the majority have noted a material reduction in the secretory response to histamine after resection of the vagus nerves. If this is so, it suggests that the presence of acetylcholine, the chemical mediator of parasympathetic impulses, potentiates the action of histamine. Stein and Meyer refer to evidence reported by Necheles et al.²² and by Gray and Ivy²³ indicating that this is the case. It therefore would not be surprising if after resection of the vagus nerves the secretory response to histamine was decreased. It is apparent from the observations of Wangenstein et al.²⁴ that epinephrine potentiates the action of histamine. There is evidence also that in low concentration, epinephrine potentiates the action of acetylcholine.²⁵ In other words, it is conceivable that the antral factor in man, presumably a histamine-like substance if not histamine, the vagal factor, presumably acetylcholine, and the sympathetic factor, presumably an epinephrine-like or sympathin-like substance, not only play independent roles in gastric secretory mechanisms but also may potentiate one another.

Naide and Sayen²⁶ have described a method of study that enables them to place patients with peripheral vascular disease into one of two groups on the basis of basal vascular tone. A person is regarded as having high vascular tone if the tips of the digits of the hands cool to below 25°C after fifteen minutes' exposure to a constant room temperature of 20°C, unclothed except for a light gown. If the digits do not cool to this level the subjects are regarded as having low vascular tone. The authors believe that patients in the latter group will develop adequate collateral circulation in the presence of obliterative vascular disease of the lower extremities, whereas those who have high vascular tone will not. It is their practice to recommend sympathectomy for patients with high vascular tone and

conservative treatment for those with low vascular tone and obliterative vascular disease. The principle of this method of study is logical and is one that I have used for many years.⁹ By study of the vascular responses of a patient to a cool environment it is possible to divide persons into various categories according to the activity of their vasoconstrictor mechanism. In deciding whether sympathectomy will improve the peripheral circulation in a given case, what one really wishes to know is to what extent vasoconstriction of sympathetic origin is capable of reducing the peripheral blood flow. In discussing his experiences with the basal vascular tone test of Naide and Sayen,²⁶ Rector²⁷ pointed out that the various tests in common use today depend upon the demonstration of an increase in circulation after blocking of the sympathetic supply to an extremity. These do not measure the degree of vasoconstriction primarily but indicate whether the denervated vascular bed is capable of maximal vasodilatation. The fact is that there are patients whose peripheral circulation can be greatly reduced by vasoconstriction but cannot dilate maximally in the absence of neurogenic vasoconstriction. They can be helped by sympathectomy but might not be regarded as suitable for this operation on the basis of usual tests. Some method of study that indicates the degree to which the circulation can be reduced by the sympathetic vasoconstrictor mechanism is very much needed in the study of peripheral vascular disorders.

Considerable interest is being displayed in the use of drugs that are sympatholytic — that is, capable of blocking sympathetic impulses, both as diagnostic tools and as therapeutic measures. Collier et al.²⁸ discuss their experiences with the use of tetraethyl ammonium chloride as an adjunct in the treatment of peripheral vascular disease and other painful states. Grimson and his associates²⁹ discuss the effects of priscol on peripheral vascular diseases, hypertension and circulation in patients.

In general, it can be stated that sympatholytic drugs vary in their blocking capacity, the duration of the effect, untoward side reactions and toxic manifestations. Furthermore, by contrast with procaine block or regional sympathectomy their action is diffuse and is not confined to the particular area of the vascular bed that one may be primarily interested in. Both in diagnosis and in therapy, one is concerned with increasing the blood flow to a certain area. This blood must be diverted from other areas for the maximal effect to be obtained. If only the vascular area in question is affected by therapy, the amount of blood borrowed from other areas will be comparatively slight. If many vascular areas are affected by therapy it is only reasonable to believe that the amount of blood diverted to the area in question will not be maximal. Consequently, the therapy will not be as effective. In this problem one is confronted with a considera-

close to, almost within, the spinal nerves. They varied in size, sometimes being apparent to the naked eye but more often being microscopic. These are referred to as intermediate ganglions. Skoog refers to Wrete's study of embryos, in which such ganglions were found principally in relation to the lumbar and brachial plexus, and sporadically in other segments. He considered that they arose from the sympathetic ganglions. Pick and Sheehan,⁶ in a detailed discussion of sympathetic rami in man, also referred to ganglions placed upon the course of rami as being surprisingly common, particularly in the lumbar region. Other studies of the anatomy of the lumbar chain^{6, 7} have emphasized the marked variations in the location of the lumbar ganglions themselves from person to person and on the two sides of the same person but did not describe these intermediate ganglions. From a practical point of view, the existence of intermediate ganglions would explain failure to denervate certain areas following conventional sympathectomies. It seems advisable to remove as much of the communicating rami as possible in the performance of a sympathectomy. Under certain circumstances supplementary anterior-root section might be advisable.

Ray et al.⁸ have also made important observations concerning the origin of the sympathetic nerves to the pupil and upper extremity. By stimulating anterior roots during the course of laminectomies they have determined that the fibers to the pupil arise from the eighth cervical to the fourth dorsal segment, most commonly from the first to second dorsal. They also found that fibers to the upper extremity in man arise from the second to the ninth dorsal segment. In only 1 of 16 cases was there any outflow from the first dorsal segment. They found that if any one of the anterior roots from the second to the ninth dorsal was not divided, denervation of the upper extremity was incomplete. The usual technic for denervation of the upper extremity,⁹ which consists in division of the anterior roots of the second and third dorsal segments and usually the fourth dorsal, as well as section of the sympathetic trunk below the third or fourth dorsal, makes adequate provision for denervation of the upper extremity in most cases. It is apparent, however, that some residual activity may be expected in about 1 in 16 cases.

Grimson¹⁰ has demonstrated clearly that the vagus nerves do not carry pain sensation from the abdominal viscera since stimulation under spinal anesthesia did not cause abdominal pain. Ray and Neill¹¹ have demonstrated that thoracolumbar sympathectomy abolishes pain from the abdominal viscera, confirming in part the observations of Bentley and Smithwick.¹² It therefore seems clear that the pain relief that follows resection of the vagus nerves for peptic ulcer is not related to the

division of pain fibers. It is clear that these are contained within the splanchnic nerves.

Pick and Sheehan⁵ have demonstrated that the gray communicating rami are situated proximal to the white, at least in the thoracic region. Although of no clinical importance, this observation will necessitate the revision of the drawings in standard textbooks. The authors have also determined that the most common level of origin of the highest component of the great splanchnic nerve was the sixth thoracic ganglion. In 25 human dissections this branch arose from the sixth ganglion in 11, the seventh in 7, the eighth in 4 and above the sixth in 3 cases. This is in keeping with clinical experience. Since visceral fibers of consequence do not leave the great splanchnic nerve above the ninth or tenth thoracic level, these findings do not appear to lend support to current efforts to extend thoracolumbar sympathectomy in an upward direction in the treatment of hypertension.

Several careful studies of the anatomic arrangement of the vagus nerves in the supradiaphragmatic and infradiaphragmatic areas have been made.¹²⁻¹⁸ One gathers the impression that the fibers are indistinct in 10 to 15 per cent of cases and might easily be missed. The number of incomplete resections of the vagus nerves as judged by a secretory response to insulin hypoglycemia after operation, reported in the literature to date, approximates this figure. On anatomic grounds, the authors cited are equally divided concerning the best surgical approach to these nerves in the treatment of peptic ulcer. Half favor the transthoracic and half the transabdominal approach. Most surgeons experienced with both favor the latter, not only because it seems to be equally satisfactory from an anatomic point of view but also because it permits inspection of the lesion and supplementary gastric surgery if indicated. It is essential that surgeons appreciate all the anatomic variations of the vagus nerves if incomplete resections are to be reduced to a minimum. It is important also to realize that the identification of all the fibers of the vagus nerves depends to no small extent upon the surgeon's sense of touch.

PHYSIOLOGY

After resection of the vagus nerves, decreased peristalsis and delay in emptying of the stomach are regularly observed. These findings are apparent from both kymographic tracings¹⁷ and roentgenographic studies.¹⁸ In some cases motility may return toward normal in a few months. In others, abnormalities may exist for years.¹⁹ Emptying of the stomach may be delayed in the absence of pyloric obstruction owing either to stenosis or to pylorospasm. It appears to be caused by the intact sympathetic supply that inhibits the tone and peristalsis of the stomach and intestine. Peristalsis may be increased and emptying improved by the use of

in the dependent position after blanching has been induced by elevation of the extremity. If flushing begins in twenty seconds or less, one can be quite certain that the collateral circulation is adequate.

Sympathectomy for peripheral vascular disease is contraindicated, then, if the general cardiovascular status of the patient is poor or if the circulation of the extremity fails to improve after temporary interruption of its vasoconstrictor supply, except in cases in which there is adequate cooling of the digits in a cool environment associated with satisfactory collateral circulation. If sympathectomy is performed in poorly selected cases it will not only fail to improve the circulation but, as pointed out in recent years by Atlas³⁶ and Freeman,³⁷ may precipitate gangrene. Both these authors have reported cases in which the circulation of the foot was decreased after sympathectomy. They attributed this to the shunting of blood away from the capillary bed by the opening of arteriovenous shunts that followed sympathectomy. Freeman considered this most likely to occur in patients with low vascular tone. A study of his case reports suggests that while this may have been a factor, the history and symptoms indicated that a recent acute vascular occlusion occurred in 3 cases. The fourth had an injury to the foot, with fractured metatarsal bones. This suggests that the collateral circulation was inadequate at the time of operation. The 3 patients described by Atlas had poor collateral circulation, and 1 had an acute thrombosis of the femoral and popliteal arteries. The importance of an adequate collateral circulation as a prerequisite to sympathectomy in the presence of obliterative vascular disease of the main vessels cannot be overemphasized.

The recent development of satisfactory technics for more detailed clinical study of the circulation by plethysmography will no doubt further improve the selection of cases for sympathectomy. Apparatus designed by Burch³⁸ and Goetz³⁹ appears to be very satisfactory.

CAUSALGIA

Among the sequelae of penetrating wounds with injury to peripheral nerves is a remarkable symptom complex to which the term *causalgia* was applied by Mitchell, Moorhouse and Keen⁴⁰ in 1864. Their patients were soldiers in the Civil War, and their description of the symptom complex that certain persons develop after peripheral-nerve injuries is regarded as a classic. Recent discussions of this matter indicate that there are descriptions of the syndrome in the literature that antedated that referred to above but to which no name was applied. Until recent years, the cause and treatment of the disorder remained a mystery, and those who suffered from it were often regarded as having a psychosis or as being malingerers. Several years ago Homans⁴¹ wrote an excellent discussion of the

syndrome. He emphasized the role that the sympathetic nervous system played in the disorder and the efficacy of interrupting sympathetic pathways by procaine block or by sympathectomy as a therapeutic measure.

Every war has produced a new group of these cases, but it was not until World War II that effective therapy was available. The policy of concentrating cases that presented particular problems and required special treatment in surgical centers had much to do with their effective management. As a result, various reports emanating from these centers have done much to clarify the signs and symptoms and the proper management of such cases. Since examples of *causalgia* are seen from time to time among the civilian population it seems worth while to summarize the literature that has appeared as a result of the last war. Excellent discussions have been published by Spiegel and Milowsky,⁴² Mayfield and Devine,⁴³ Ulmer and Mayfield,⁴⁴ Albritten and Maltby,⁴⁵ Rasmussen and Freedman,⁴⁶ Kirklín, Chenoweth and Murphy,⁴⁷ Freeman,⁴⁸ Shumacker^{49, 51} and White, Heroy and Goodman.⁵² These authors saw varying numbers of cases, and the interval between injury and treatment differed. There were variations in the signs and symptoms in the different groups, and certain features were emphasized particularly by some authors and to a lesser extent by others. It is possible, however, from these excellent discussions to obtain a fairly accurate composite picture of the problem as a whole.

Definition

Causalgia may be defined as a syndrome associated with a penetrating wound with a lesion of a peripheral nerve containing sensory fibers manifested by pain in the extremity, hand or foot primarily, that is accentuated by certain disturbing features in the patient's environment. The term should not be applied to allied post-traumatic disorders unassociated with penetrating wounds and peripheral-nerve injury.

Incidence

It is estimated that this syndrome develops in 2 to 5 per cent of peripheral-nerve injuries. It is not known why other persons with similar nerve injuries do not develop *causalgia*.

Onset

The pain apparently may begin immediately or within a few hours of injury. Perhaps 50 per cent of cases fall into this category. About 25 per cent of patients state that the pain begins in the course of a week, and about 15 per cent in the course of one to three weeks, and in the others it develops in the course of one to several months after injury.

tion of the relative merits of regional sympathectomy and more generalized sympathectomy both as diagnostic and as therapeutic measures De Bakey et al³⁰ have discussed the matter from this point of view and state

Peripheral vascular disease is characterized by a disturbance of, or actual diminution in, the normal amount of circulating blood which reaches the part, and its effective therapy is based on improvement in the circulation or an increase in the blood supply to the part. Therapeutic measures designed to produce dilatation of the entire vascular bed do not seem rational for a disease state localized to a single peripheral part, but, in spite of the illogic of the attempt, there are numerous reports concerning the production of generalized vasodilatation as a form of therapy for peripheral vascular disease involving portions of the body. The results of these efforts are open to question, theoretically such measures are inefficient. Moreover, even if an effective agent, i. e. with the ability to produce maximum vasodilatation, for this purpose did exist, its effect would be dangerous, the reaction would be shock-like, and the original purpose of increasing the blood supply to the local part would be completely defeated.

In view of the lack of rationale in peripheral vascular disease of the use of agents intended to produce generalized vasodilatation, quite aside from their ineffectiveness and theoretical dangers, the attention should be concentrated on measures which produce local vasodilatation. The best of these measures, in our experience, is sympathetic denervation of the affected part. It is rational because it conforms with the principles of hemodynamics just laid down, it produces local vasodilatation insuring maximum improvement in the local circulation of the diseased part. It is safe, because it does not reduce the arterial blood pressure or produce serious systemic disturbances by the sudden creation of a disproportion between the total volume of the vascular bed and the total blood volume. Finally, it is effective.

Indeed, we have yet to find a general vasodilator which could produce in a local part, such as the toes, fingers, foot, hand, or extremity, vasodilatation equal in degree or duration to that produced by sympathetic denervation of the part.

Important physiologic observations have been reported by Wilkins et al^{31, 32} concerning the vasomotor reaction of the visceral vascular bed. These have to do primarily with the problem of hypertension. For the first time, a method of study has been devised that permits one to tell to what extent the visceral vascular bed has been denervated. By means of optically recorded readings of blood pressure from the brachial or femoral artery they have shown that vasomotor responses following various stimuli are completely abolished after thorough denervation of the splanchnic bed but are not abolished after partial denervation of this area. This procedure will be helpful in judging the relative merits of various surgical technics in the treatment of hypertension and in the study of regeneration of sympathetic nerves to the viscera. It also has been useful in studying the effect of various drugs upon the visceral vascular bed.

CLINICAL APPLICATION

Obliterative Vascular Disease of the Lower Extremity

The fact that the circulation of an extremity can be improved by sympathectomy in the presence of known obliterative disease both of the arterio-

sclerotic variety and in patients having thromboangitis obliterans is now quite generally recognized. The selection of patients for this form of therapy is of great importance. One must not only consider the extremity in question but also evaluate the cardiovascular status as a whole in arriving at a decision for or against sympathectomy. If evidence of severe cardiac, cerebral or renal involvement is detected, sympathectomy is contraindicated. The circulatory status of the extremity in question should always be subjected to detailed study before operation. Sympathectomy should never be performed without first obtaining evidence that the procedure is almost certain to be helpful. Of the methods of study available, temporary interruption of the sympathetic supply to the extremity by procaine block and the demonstration that a definite improvement in circulation results therefrom are commonly employed. De Takats et al³³ prefer paravertebral sympathetic block, and Cooper and Harris³⁴ use spinal anesthesia. Of the other methods of study, reflex vasodilatation by the Gibbon and Landis³⁵ technic and, more recently, the use of sympatholytic drugs should be mentioned. If any of these tests give definite evidence of temporary improvement in circulation one can be quite certain that the effect of operation will be worth while. As pointed out above, interruption of the sympathetic supply to the area in question by procaine block is likely to give more reliable information than tests that produce general vasodilatation. The latter may not cause an increase in blood flow to the extremity in question because of the shifting of blood to other areas where vasodilatation occurs more readily. The area being studied may even become cooler rather than warmer. This can lead the uninitiated to an erroneous conclusion concerning the advisability of sympathectomy. Not infrequently, this occurs in patients with a high degree of sympathetic tone in the extremity in question — in other words, in patients best suited for sympathectomy. It is wise not to attach the same significance to a negative as to a positive response to the tests mentioned. When the response is negative, one should be guided by the degree of cooling of the extremity in a cool environment — in other words, by evidence of the capacity of the vasoconstrictor mechanism to decrease blood flow through the extremity. It has been my experience that if the tips of the digits of the extremity in question cool to below 75°F after one hour's exposure to a room temperature of 68°F, and if the collateral circulation to the extremity is adequate, operation will be helpful. This conclusion is similar to that reached by Naide and Sayen²⁶ except that I prefer to study the extremity in question rather than to draw conclusions regarding the lower extremities from a study of the upper extremities only. The best simple test of collateral circulation is the time required for the tips of the digits to begin to flush

removed. Periarterial sympathectomy was found to be as ineffective as it has been in the past.

Mechanism of Pain

In spite of the fact that interruption of the sympathetic supply to an extremity almost always relieves causalgia, the mechanism for the production of pain and the explanation for its relief are not known. Some observers believe that the pain is caused by the stimulation of afferent somatic fibers at the point of peripheral-nerve injury by sympathetic efferents. This theory, which was proposed by Doupe, Cullen and Chance,⁵³ is in keeping with the explanation that failures following incomplete denervation of the site of injury could be due to the persistence of efferent sympathetic pathways having their synapses in intermediate rather than in the paravertebral ganglions. Other observers believe that the relief of pain is due to the interruption of afferent fibers carrying pain sensation from the extremities that pass through the sympathetic trunks and ganglions before entering the posterior roots to reach higher levels of pain perception. There has always been considerable doubt of the existence of such pathways from the extremities of man although some recent evidence has been presented by Treadgill⁵⁴ that they exist in animals. Whatever the explanation for causalgia may be, it is clear that sympathectomy is a very effective therapeutic measure.

ESSENTIAL AND MALIGNANT HYPERTENSION

In a discussion of early results of splanchnicectomy for hypertension de Takats⁵⁵ divides 250 cases followed one to six years into three groups designated as early, marked and too advanced respectively. There were 55 cases in the first, 171 in the second, and 24 in the third group. He regarded the results as satisfactory in 85 per cent of the first, in 75 per cent of the second, and in none of the third group. Failures in the first group were thought to be due to inadequate denervation in 2 cases, and were unexplained in 6. Failures in the second group were regarded as due to inadequate surgery in 5, heart failure in 7, and cerebral accidents in 6, and 13 cases were unexplained. All the failures in the third group were explained by poor case selection — that is, operation upon patients in a near-terminal stage of the disease.

Discussions of early results and the selection of cases for surgery have been reported by Hinton⁵⁶ and Smithwick.⁵⁷ The former based his discussion upon a series of 375 cases followed for six months to five years, and the latter upon a series of 439 cases followed for one to five years or more. In both papers, the circumstances under which the results were most likely to be unsatisfactory were discussed in considerable detail from the viewpoint of the individual patient. All these discussions must be regarded as preliminary, since no final evaluation

of the surgical treatment of hypertension can be made until an adequate number of cases have been followed for at least five years, and preferably longer. A study of early results is, however, worth while, since the obvious failures — namely, patients who fail to survive for more than a few years after operation — can be detected and eliminated as candidates for surgical treatment in the future.

So far only two articles have appeared in the literature in which the status of a sizeable number of surgically treated patients followed for five years or more has been discussed. Peet and Isberg⁵⁸ reported upon 437 cases followed for five to eleven years, and Smithwick⁵⁹ upon 256 cases followed for five to ten years. In both series the mortality rates compared favorably with those published for nonsurgically treated cases. In the latter series⁵⁹ the mortality rates for cases grouped according to the grade of eyegrounds was considerably lower than that reported by Keith, Wagener and Barker⁶⁰ for nonsurgically treated patients. The mortality rates for both sexes were considerably lower than those for nonsurgically treated patients reported by Janeway,⁶¹ Blackford, Bowers and Baker,⁶² Keith, Wagener and Barker⁶⁰ and Rasmussen and Boe.⁶³ The rates for cases when arranged by resting diastolic-blood-pressure levels were also much lower in the surgical series than in that reported by Rasmussen and Boe. The progress of cardiovascular disease as judged by the course of the electrocardiogram five years or more after operation compared very favorably with that of the nonsurgically treated patients reported by Canabal et al,⁶⁴ as well as the cases reported by Rasmussen and Boe. The differences observed in this and the other comparisons referred to were large enough to be of statistical significance.

To date, nothing has appeared in the literature to give an adequate indication of the prognosis for a specific hypertensive patient whether untreated or treated medically or surgically. Such data should shortly be available for surgically treated patients followed for five to ten years and divided into subgroups in which the most important variable factors that exist in this disorder are held constant. It will then be possible to give a reasonably accurate prognosis for a particular patient. It is desirable that similar data be accumulated for nonsurgically treated patients so that more accurate comparisons can be made of the results of various therapeutic measures. This will be most helpful in the selection of the best form of therapy for a particular patient.

Articles have appeared relating to surgical technique.^{65, 66} These have to do primarily with extending the magnitude of operations for hypertension. The morbidity and mortality seem to be increased. It is doubtful whether the results will be improved sufficiently by more radical surgery to compensate for these untoward effects.

Nature

The pain is most frequently described as burning in nature. In some cases, however, no thermal characteristics are noted. In the great majority, about 90 per cent, it is constant. In occasional cases it is intermittent. The pain may be throbbing, aching, twisting, knife-like, stabbing or crushing, in addition to or instead of being burning. An essential feature of the pain is that it is intensified by various factors such as moving or touching the involved part, a sudden jarring of the bed, loud noise, emotional excitement, touching the part with slick objects such as sheets of paper or with a dry but not with a wet finger, touching the patient's body at any point, looking up in the air at high objects, extremes of temperature, or the sound of certain words such as paper or slick. Most of these stimuli are thought to cause increased sympathetic outflow to the extremity.

Distribution

The pain is most commonly associated with an incomplete injury of a peripheral nerve although there apparently are a few proved cases of causalgia following complete division of nerves. It is generally confined to or most intense in the sensory distribution of the nerve injury but may spread beyond the area.

Severity

The pain was slight in about 20 per cent, moderately intense in 35 per cent, severe in 35 per cent and excruciating in 10 per cent of the cases.

Nature of Nerve Injury

No characteristic lesion has been described. There is nothing different about the nerve injury that distinguishes it from identical injuries not associated with causalgia.

Vasomotor Manifestations

Two types of vasomotor changes are described, vasodilatation and vasoconstriction. In occasional cases the vasomotor status was regarded as normal. While it is possible that the original vasomotor status persists in a given case, the evidence suggests that vasodilatation may characterize the earlier stages of the disorder and may be replaced by vasoconstriction after a number of months. In the stage of vasodilatation the skin was usually pink, warm, dry, scaly and velvety, with increased growth of hair. In the stage of vasoconstriction the skin is described as being cold, thin, glistening and sweating profusely, with decreased growth of hair. Some form of moist dressing was preferred by most patients. In general, cool applications were preferred in the stage of vasodilatation, and warm in the stage of vasoconstriction.

Trophic Changes

So-called trophic changes in the skin, subcutaneous tissues, nails, joints and bones occurred frequently and apparently were closely related in both time of onset and severity to the intensity of the pain and the degree of disease. These changes were a serious handicap to rehabilitation once the pain was relieved. The importance of early diagnosis and treatment is repeatedly stressed.

Treatment

It seems generally agreed that therapy directed to the region of the nerve injury should not be the primary procedure unless some indication for exploration other than causalgia is present. Neurolysis rarely helped, and resection and suture only occasionally relieved the pain. All authors found that paravertebral procaine block of the sympathetic supply to the extremity resulted in complete or almost complete relief of pain in the great majority of cases. In some of the milder forms, one or several blocks resulted in cure. This applied to about 20 to 30 per cent of cases. In general it was noted that if the relief exceeded the duration of the anesthetic, treatment by blocking was apt to be successful. If the duration of relief corresponded to the duration of the anesthetic, one and a half hours or less, and if the relief on repeated blocking was the same or of shorter duration, this form of treatment was almost always unsuccessful. Under these circumstances, the extremity was sympathectomized. The results of sympathectomy in 75 per cent of the cases was excellent. In 20 per cent the result was good. Failures were reported in less than 5 per cent of cases. The upper extremity was involved in 60 per cent, and the lower in 40 per cent. In general, the results of the treatment were a little better in upper-extremity causalgias than in those of the lower extremity. The procedure most frequently utilized in denervation of the upper extremity was the so-called preganglionic section. This results in a more thorough denervation of the entire upper extremity than is obtained in the lower extremity after the conventional lumbar sympathectomy. This point, as well as the possible role of intermediate ganglions in explaining incomplete denervation of the thigh following operations of any magnitude upon the thoracolumbar chain, was emphasized above. Some authors believed the site of injury as well as the area of referred pain should be completely denervated. A few cases were reported in which extension of the sympathectomy upward for several segments, after failure to relieve lower-extremity causalgias that followed removal of the second and third or first, second and third lumbar ganglions, resulted in relief. In occasional cases, the pain was not relieved until thrombosed segments of arteries or aneurysms had been

THE ULCER PROBLEM

Numerous reports of early experiences, both favorable and unfavorable, with resection of the vagus nerves alone and in combination with other operations upon the stomach continue to appear in the literature.⁶⁷⁻⁷³ Dragstedt et al.⁷⁴ correctly emphasize the need for special care in the postoperative management of these patients because of the marked disturbance of gastric motility that almost invariably occurs in the early postoperative period. Decompression of the stomach for several days after operation is essential. Feedings should consist of small quantities of clear fluids at first, with frequent estimations of gastric residue. Diet should be increased very gradually over a period of several weeks. If mechanical obstruction of the pylorus is apparent from the history, by x-ray study or by inspection of the lesion at operation, the authors believe that gastroenterostomy should be done at the time of the neurectomy. They regard their results to date as satisfactory and find no indications at present for gastric resection either alone or in combination with vagus resection in the treatment of duodenal ulcers requiring surgery.

Colp and his associates⁷⁵ compared the early results of subtotal gastrectomy alone and combined with vagus resection in two series of patients. The morbidity was increased by the combined procedure, but there was no mortality in either series. The combined procedure was much more effective in modifying both neurogenic and chemical gastric secretory mechanisms as judged by the effect upon gastric acidity. Achlorhydria was present in the fasting secretion as well as in response to food, insulin and histamine in a high percentage of the cases. If this persists, and if gastric acidity is as important as most observers believe it to be in the genesis and perpetuation of peptic ulcers, it seems likely that the combined procedure will lower the incidence of recurrent gastrojejunal ulceration. If it is not associated with a higher incidence of untoward side effects than radical gastrectomy alone, it may prove to be worth while.

To date, too few cases have been followed for an adequate period for one to reach any final conclusions regarding the relative merits of vagus resection alone, combined procedures and gastric resection only in the treatment of duodenal ulcers. Nothing but time combined with careful preoperative and postoperative studies can settle this problem. If there is any agreement upon any aspect of this matter, it seems to be the opinion of most that resection of the vagus nerves is particularly indicated in the management of gastrojejunal ulceration following subtotal gastrectomy. There is less agreement about the value of resection of the vagus nerves for gastrojejunal ulceration after gastroenterostomy. As a primary procedure, many believe that vagus resection combined with posterior gastroenterostomy is

justifiable in the management of obstructing or complicated ulcer problems when the risk of resection would be increased by difficulties encountered in the management of the duodenal stump, or in obstructed patients in extremely poor condition. Some surgeons believe that vagus resection may properly be combined with subtotal gastrectomy in patients whom experience has shown to be most susceptible to recurrent ulceration after subtotal gastrectomy alone — namely, those with recurrent hemorrhages and those with unusually high preoperative acidity. The frequency with which vagus resection alone may be considered varies greatly in different clinics. In some, so-called refractory nonobstructing ulcers seem to be quite common. In others, nonobstructing ulcers requiring surgical treatment are rare. One point upon which all authors are agreed is that the place resection of the vagus nerves will occupy in the management of duodenal ulcer is still in the investigative phase. It certainly has stimulated great interest in this subject and has resulted in much more careful study of each patient than was formerly the case. In the end, this can only react to the advantage of the ulcer patient.

Excellent reviews of surgery of the autonomic nervous system have recently been published by White,⁷⁶ Grimson⁷⁷ and Goetz.⁷⁸ These articles together cover almost every phase of the subject and contain extensive bibliographies.

I was asked yesterday by one of our officers to summarize what has happened since I might say first that the bill that you received and the method of producing it were decided upon by a meeting of our delegates and the officers of the Society, and they all agreed that the method of sending the bill, the printed material that you saw on it, was all right. That vote was unanimous.

I had to anticipate a certain amount of criticism, perhaps, to the effect that the Society's office help and the salaried officials ought not to spend too much time or money or effort in the collection of this money. They are being paid to work for the Massachusetts Medical Society and not for the American Medical Association. That is a question, and I anticipated that criticism possibly by seeing to it that none of this work has been done by the officers or the salaried or wage-earning help of the Society.

The printing was done outside, and the American Medical Association paid the bill.

The mailing was done by a professional mailing concern, at the expense of the American Medical Association. And the checks, as they come back, are accounted for by an extra clerk, whose salary will be paid by the American Medical Association. So that all we have done is think about it and plan the routine of doing it. No real work has been subtracted from the time that we are supposed to be spending for the Massachusetts Medical Society.

The Secretary then moved that the Council ratify the action of the Executive Committee in this matter. The motion was seconded.

Dr Lawrence R Dame (Franklin) emphasized the points brought out by the Secretary and reviewed the point of view of the Executive Committee.

Dr John J Curley (Worcester North) stressed the fact that the American Medical Association had no available funds for an educational campaign and gave the point of view of the delegates that this was an emergency.

The President stated the question and suggested a vote by ballot. Dr Scarcello (Worcester) moved that the vote be taken by voice. The motion was seconded, and it was so voted. The President then put the question of ratification to a vote, and it was carried unanimously.

Committee on Public Relations—Dr Harold R Kurth, Essex North, *Secretary*

Dr Kurth presented the report (Appendix No 4) and moved its acceptance. The motion was seconded, and it was so voted.

Dr Kurth then stated there were two items in the report that required action by the Council. The first was the request of Dr Conlin to attend all committee meetings to gather information he might desire for the proper functioning of his office. As a result of discussion in the Executive Committee, Dr Kurth presented for approval the resolution appearing in the Executive Committee report as follows:

That the Director of Medical Education and Information shall be a non-voting member of all committees of the Massachusetts Medical Society. He shall be privileged to distribute the information acquired at such meetings after written approval of the Committee or its chairman, and further, if this action is approved, that it be referred to the Committee on By-laws and Council Rules for their action.

Dr Ralph R Stratton (Middlesex East) made a motion to amend the resolution by inserting after the word "Committees," the words "with the exception of the Committee on Ethics and Discipline." This amendment to the resolution was seconded, and after some discussion it was so voted. The President then stated the resolution as amended, and it was so voted.

Dr Kurth then stated the second matter for consideration—namely, the code concerning matters of publicity so far as they concerned physicians and hospitals.

This code was submitted to the committee by Dr Conlin as it came from the Executive Committee of the Massachusetts Eye and Ear Infirmary. The Committee on Public Relations accepted the code as revised by the Committee on Ethics and Discipline, to which it had been referred. The Executive Committee believed that it should be resubmitted to the Committee on Ethics and Discipline for further consideration. Dr Kurth made a motion to resubmit the code. The motion was seconded.

Dr McCarthy (Norfolk) said he believed that the Society should have some control over certain publicity by hospitals. Dr Kurth stated that he believed that the Society could have no such control. The President stated the motion, and it was approved unanimously.

Dr Kurth moved for acceptance of the report as a whole, and it was so voted.

Committee on Legislation—Dr Solomon L Skvirsky (Norfolk), *Chairman*

Dr David L Belding (Norfolk South) presented the report (Appendix No 5) in the absence of the chairman. Dr Belding made a motion that the Council approve the recommendation of the committee that the President annually appoint a subcommittee on national legislation, that all reports and actions of the subcommittee be cleared through the Committee on Legislation and that the President make such additional emergency and temporary appointments for handling national legislation as, in his opinion, the situation demands. The motion was seconded, and it was so voted.

Dr Belding then made a motion that the President appoint a committee of five to meet with the Massachusetts Nurses Association. The motion was seconded, and it was so voted. Dr Belding moved acceptance of the report as a whole. The motion was seconded, and it was so voted.

Committee on Arrangements—Dr Harold G Giddings (Middlesex South), *Chairman*

Dr Giddings presented the report (Appendix No 6) as informational and moved its acceptance. The motion was seconded, and it was so voted.

MASSACHUSETTS MEDICAL SOCIETY

PROCEEDINGS OF THE COUNCIL

Stated Meeting, February 2, 1949

A STATED meeting of the Council was called to order by the president, Dr Daniel B Reardon, Norfolk South, on Wednesday, February 2, 1949, at 10 30 a m in John Ware Hall, 8 Fenway, Boston

Two hundred and thirty-four councilors (Appendix No 1) were present

The President then announced the following appointments

To the Section on Pathology and Physiology

Dr Monroe J Schlesinger, *Chairman*

Dr Donald A Nickerson, *Secretary*

To the Council

Dr Joseph P Marnane, Worcester North

To the Committee to Meet with the Officers of the Bay State Medical Rehabilitation Clinic

Dr Alexander P Aitken

The President asked for approval of these appointments, and it was so ordered by vote of the Council

The Secretary presented the record of the October 6, 1948, meeting of the Council as published in the *New England Journal of Medicine*, issue of December 2, 1948, and moved its acceptance The motion was seconded, and it was so ordered by vote of the Council

REPORTS OF COMMITTEES

Executive Committee—Dr H Quimby Gallupe, Middlesex South, *Secretary*

The Secretary presented the minutes of the meeting of the Executive Committee held on January 5, 1949, as mimeographed (Appendix No 2) and mailed to the councilors He drew the attention of the councilors to the change of time of the committee meeting, the length of it and the expanded report of discussions

The Secretary then presented the report of the Committee on Membership (Appendix No 3) and moved the approval of the recommendation concerning new categories of membership The motion was seconded, and it was so voted without discussion

The Secretary then said that there had been no business referred to the Committee by the Council and that there was only one matter of new business—namely, that concerning the American Medical Association assessment He reviewed the information concerning this as follows

Immediately following the Interim Session of the American Medical Association in St. Louis on December 1, I received the following telegram from the Secretary of the American Medical Association

Recent Interim Session House of Delegates unanimously decided to assess each member of American Medical Association \$25 00 You are requested to collect this assessment through your county units or any other way you desire Bill association for any extra expense in connection with the collection

That seemed to be rather a big job for the secretary of this society to do all by himself and without any particular authority from this society to act My first attempt was to find out if this assessment by the American Medical Association was proper, according to their by-laws, and I can assure you that it is, so far as we are aware, because last summer at the annual session of the American Medical Association that organization produced new by-laws, which were accepted by the House of Delegates, Article 2 of which reads

Funds may be raised by an equal assessment of dues of not more than \$25 annually on each of the active members on recommendation by the Board of Trustees and after approval by the House of Delegates

I then approached the delegates of the Society who had attended the Interim Session I was at St. Louis myself, but did not attend the meeting of the House of Delegates. I was there for another purpose

Our delegates assured me that they did vote unanimously for this assessment and that they did so because the American Medical Association was without funds and had been for some time, that last year the American Medical Association had gone into the red by a considerable number of thousands of dollars, and that all their money came from subscriptions to their various journals, some of which operated in the red

They were assured that this assessment was decided upon by the trustees of the American Medical Association previous to November 2, when Mr Truman was elected It was not influenced particularly by politics or proposed legislation in the Eighty-First Congress The money was needed anyway, and our delegates assured us that it was their complete understanding that this assessment was necessary There was a certain amount of emergency to it, and it was their understanding that it was completely voluntary and that no penalty could be dealt to anyone not subscribing to this assessment.

Now, our delegates are unanimous on that opinion, and as you well know, I have stated that publicly It is the opinion of the officers of the Society that that is the story and there is nothing in the by-laws of the Society that makes it possible to punish anybody for not paying an American Medical Association assessment Therefore, it seems logical to believe that it is voluntary and I am certain that the Society and the American Medical Association do not want your money or anybody else's money if it is not given voluntarily

I am trying, as you can see, to answer any of the questions that have been raised concerning the issue over the last two months

Having decided that that was the whole story, I still was not willing to act as an agent of the American Medical Association without some degree of authority from the Society and I did not think it was wise to wait for a Council meeting I made the proposal to the Executive Committee that they authorize me to act as an agent for the American Medical Association in the collection of this money, and they did so unanimously, after first voting that this was an emergency, under the by-laws the Executive Committee has the right to authorize any officer of the Society to act in an emergency So the Executive Committee acted within their rights, and after careful discussion, which lasted a considerable time, they voted unanimously to do what the American Medical Association requested me to do

I was asked yesterday by one of our officers to summarize what has happened since I might say first that the bill that you received and the method of producing it were decided upon by a meeting of our delegates and the officers of the Society, and they all agreed that the method of sending the bill, the printed material that you saw on it, was all right. That vote was unanimous.

I had to anticipate a certain amount of criticism, perhaps, to the effect that the Society's office help and the salaried officials ought not to spend too much time or money or effort in the collection of this money. They are being paid to work for the Massachusetts Medical Society and not for the American Medical Association. That is a question, and I anticipated that criticism possibly by seeing to it that none of this work has been done by the officers or the salaried or wage-earning help of the Society.

The printing was done outside, and the American Medical Association paid the bill.

The mailing was done by a professional mailing concern, at the expense of the American Medical Association. And the checks, as they come back, are accounted for by an extra clerk, whose salary will be paid by the American Medical Association. So that all we have done is think about it and plan the routine of doing it. No real work has been subtracted from the time that we are supposed to be spending for the Massachusetts Medical Society.

The Secretary then moved that the Council ratify the action of the Executive Committee in this matter. The motion was seconded.

Dr Lawrence R. Dame (Franklin) emphasized the points brought out by the Secretary and reviewed the point of view of the Executive Committee.

Dr John J. Curley (Worcester North) stressed the fact that the American Medical Association had no available funds for an educational campaign and gave the point of view of the delegates that this was an emergency.

The President stated the question and suggested a vote by ballot. Dr Scarcello (Worcester) moved that the vote be taken by voice. The motion was seconded, and it was so voted. The President then put the question of ratification to a vote, and it was carried unanimously.

Committee on Public Relations—Dr Harold R. Kurth, Essex North, *Secretary*

Dr Kurth presented the report (Appendix No. 4) and moved its acceptance. The motion was seconded, and it was so voted.

Dr Kurth then stated there were two items in the report that required action by the Council. The first was the request of Dr Conlin to attend all committee meetings to gather information he might desire for the proper functioning of his office. As a result of discussion in the Executive Committee, Dr Kurth presented for approval the resolution appearing in the Executive Committee report as follows:

That the Director of Medical Education and Information shall be a non-voting member of all committees of the Massachusetts Medical Society. He shall be privileged to distribute the information acquired at such meetings after written approval of the Committee or its chairman, and further, if this action is approved, that it be referred to the Committee on By-laws and Council Rules for their action.

Dr Ralph R. Stratton (Middlesex East) made a motion to amend the resolution by inserting after the word "Committees," the words "with the exception of the Committee on Ethics and Discipline." This amendment to the resolution was seconded, and after some discussion it was so voted. The President then stated the resolution as amended, and it was so voted.

Dr Kurth then stated the second matter for consideration—namely, the code concerning matters of publicity so far as they concerned physicians and hospitals.

This code was submitted to the committee by Dr Conlin as it came from the Executive Committee of the Massachusetts Eye and Ear Infirmary. The Committee on Public Relations accepted the code as revised by the Committee on Ethics and Discipline, to which it had been referred. The Executive Committee believed that it should be resubmitted to the Committee on Ethics and Discipline for further consideration. Dr Kurth made a motion to resubmit the code. The motion was seconded.

Dr McCarthy (Norfolk) said he believed that the Society should have some control over certain publicity by hospitals. Dr Kurth stated that he believed that the Society could have no such control. The President stated the motion, and it was approved unanimously.

Dr Kurth moved for acceptance of the report as a whole, and it was so voted.

Committee on Legislation—Dr Solomon L. Shvirsky (Norfolk), *Chairman*

Dr David L. Belding (Norfolk South) presented the report (Appendix No. 5) in the absence of the chairman. Dr Belding made a motion that the Council approve the recommendation of the committee that the President annually appoint a subcommittee on national legislation, that all reports and actions of the subcommittee be cleared through the Committee on Legislation and that the President make such additional emergency and temporary appointments for handling national legislation as, in his opinion, the situation demands. The motion was seconded, and it was so voted.

Dr Belding then made a motion that the President appoint a committee of five to meet with the Massachusetts Nurses Association. The motion was seconded, and it was so voted. Dr Belding moved acceptance of the report as a whole. The motion was seconded, and it was so voted.

Committee on Arrangements—Dr Harold G. Giddings (Middlesex South), *Chairman*

Dr Giddings presented the report (Appendix No. 6) as informational and moved its acceptance. The motion was seconded, and it was so voted.

*Committee on Finance — Dr Robert W Buck
(Middlesex South), Chairman*

Dr Buck presented the report as printed (Appendix No 7) and moved the adoption of the first recommendation as follows

An increase of \$1500 in the salary of the Director of Medical Information and Education above that provided in your action last year by which annual increases were to amount to \$500 each year until a total salary of \$10,000 was reached. It is the opinion of the officers of the Society, the members of the original committee that chose the Director and of other representative fellows that the full salary should be paid beginning in 1949 instead of in 1952

The motion was seconded, and it was so voted

Dr Buck moved the adoption of the second recommendation as follows

I move an increase of \$1200 in the salary of the Executive Secretary, which has been requested by officers of the Society, and approved by your committee and also approved by the Executive Committee.

The motion was seconded, and it was so voted

Dr Buck then moved that the salary of the Assistant Treasurer be fixed at \$500 (no salary had been paid previously). The motion was seconded, and it was so voted

Dr Buck then moved that the Director of Medical Information and Education be provided with secretarial service at an annual cost of \$2,000. The motion was seconded, and it was so voted

Dr Buck then moved "that the increase in the budget for the Committee on Legislation be adopted, with the explanation that this increase will largely be demanded because of increased secretarial duties that will be required". The motion was seconded, and it was so voted

Dr Buck then spoke as follows

I only wish to call attention to the last paragraph and perhaps emphasize it. We have found no difficulty in using up the additional funds that have been supplied by the increase in dues. There have been so many requests and apparent real needs for the use of these funds that it becomes a little too easy to spend money. We must now realize that we have reached almost the limit of our possible expansion and that it is now up to the chairmen of all committees and to all of us to realize that we are working within our budget, but not with any great margin to spare and nobody wants to see another increase in dues or have to raise money from some other source

Dr Buck then made the motion to accept the report as a whole. The motion was seconded, and it was so voted

Committee on Industrial Health — Dr Daniel L Lynch (Norfolk), Chairman

Dr Lynch presented the report (Appendix No 8) as informational and moved its acceptance. The motion was seconded, and it was so voted

Advisory Subcommittee on Malpractice Insurance —

Dr Carl Bearse (Norfolk), Chairman

Dr Bearse submitted his report (Appendix No 9) with one correction — that is, 155 suits pending in-

stead of 147. He added that during 1947 there were 64 new suits entered in courts. Dr Bearse stated that his committee had sent questionnaires to 5530 doctors, letters were sent to 49 secretaries of medical organizations and to all companies writing malpractice insurance in Massachusetts

Dr Bearse made the motion that the Council approve the recommendation concerning "listeners". The motion was seconded. Dr John Curley stated the arguments against the motion as discussed in the Executive Committee. Dr McCarthy (Norfolk) spoke in favor of the motion. Dr Dame (Franklin) spoke against the motion. Dr Allan M Butler (Suffolk) pointed out that either the doctor or the insurance company could employ "listeners" if they wished

The President stated the motion, and it was not carried by voice vote

Dr Bearse then made a motion to approve the second recommendation concerning a panel of experts. The motion was seconded. There was no discussion. On voice vote the motion was defeated

Dr Bearse then made a motion that the Council approve the third recommendation that his committee review the testimony of members and that if the testimony were found substandard, the matter would be reported to the Committee on Ethics and Discipline. The motion was duly seconded, and it was so voted

Dr Bearse then moved that the Council approve the fourth recommendation that the insurance companies be notified of the actions of the Council in these matters. The motion was seconded

Dr Kickham (Norfolk) said he believed there was no necessity for the Council to report its actions to any insurance company. On a show of hands the motion was lost

Dr Bearse then moved for acceptance of the report as a whole. This motion was seconded, and it was so voted

The Secretary called the attention of the Council to the recommendation of the Executive Committee praising the committee for the good job it had done and hoping that it would continue to act. The Secretary moved the approval of this recommendation by the Council. The motion was seconded, and it was so voted

Committee on Emergency Medical Service — Dr Reginald Fitz (Suffolk), Chairman

In the absence of the Chairman, the Secretary submitted the report (Appendix No 10) and stated the arguments of the Executive Committee against the recommendations of the committee concerning the make-up of the committee as proposed. The Secretary made the motion that the recommendation of the Committee on Emergency Medical Service be disapproved by the Council. This motion was seconded

Dr Scarcello (Worcester) stated that he believed the committee should be a representative committee like the committees on Public Relations and Legislation

Dr Curley (Worcester North) said he believed that a group near Boston would be most effective and that if the chairman of the district committees were added to the present committee, the resulting enlarged committee would be democratic. On a show of hands, the motion to disapprove was carried.

The Secretary made a motion to approve the recommendation of the Executive Committee, which would add the chairmen of the district committees to the present committee. The motion was duly seconded, and it was so voted. The Secretary moved for acceptance of the report as a whole. The motion was seconded, and it was so voted.

Committee to Meet with the Officers of the Bay State Rehabilitation Clinic—Dr Charles H. Bradford (Suffolk), *Chairman*

Dr Bradford made the motion to approve the report (Appendix No. 11) as a whole, with its four recommendations. The motion was seconded, and it was so voted.

The President stated that he was reappointing the same committee as the now working committee and adding to it Dr Alexander P. Aitken. He asked for approval of this action. The motion was seconded, and it was so voted.

Advisory Subcommittee on Medical Education—Dr I. R. Jankelson (Norfolk), *Chairman*

Dr Jankelson made a motion to accept the report (Appendix No. 12) as informational. The motion was seconded, and it was so voted.

Committee on Diabetes—Dr Howard F. Root (Suffolk), *Chairman*

Dr Root presented the first part of the report, as printed in the Circular of Advance Information (Appendix No. 13), as informational and moved its acceptance. The motion was seconded, and it was so voted. Dr Root then moved for the approval of the resolution in the supplementary report (Appendix No. 14). The motion was seconded, and it was so voted. Dr Root then moved acceptance of the report as a whole. The motion was seconded, and it was so voted.

Committee on Blue Cross-Blue Shield Problems—Dr Charles J. E. Kickham (Norfolk), *Chairman*

Dr Kickham presented the report (Appendix No. 15) as printed. He moved that the first recommendations to have the President appoint annually a general chairman of the Blue Shield Fee Committee Chairmen be approved by the Council. The motion was seconded, and it was so voted. Dr Kickham then moved that the second recommendation, "that the Executive Director of Blue Shield annually re-

quest the Specialty Sections within the Society and the Specialty Sections without the Society to review the composition of their respective Blue Shield Fee Committees and that the Executive Director of Blue Shield suggests to the Specialty Sections a uniform method of rotating membership on Blue Shield Fee Committees," be approved by the Council. The motion was seconded, and it was so voted. Dr Kickham then moved acceptance of the report as a whole. The motion was seconded, and it was so voted.

Committee on By-Laws and Council Rules—Dr Edward P. Bagg (Hampden), *Chairman*

Dr Bagg presented the report of the committee (Appendix No. 16) as corrected. Dr Bagg made a motion to accept the report as a whole. The motion was seconded, and it was so voted. Dr Bagg then made a motion for the approval by the Council of each of the resolutions in the report. The motions were each seconded, and it was so voted.

Dr Bagg made a motion for approval by the Council of the changes in the Council rules as printed. The motion was seconded, and it was so voted.

Dr Bagg then made a motion for the approval of the preamble to the Rules. The motion was seconded, and it was so voted. Dr Bagg then moved for approval of the report as a whole. The motion was seconded, and it was so voted.

Advisory Committee to the Woman's Auxiliary—Dr John F. Conlin (Suffolk), *Chairman*

Dr Conlin submitted the report (Appendix No. 17) as informational and moved its acceptance. The motion was seconded, and it was so voted.

Dr Conlin then made the following statement:

An additional progress report concerning the Woman's Auxiliary points to 16 of the 18 district medical societies that have now approved the formation of auxiliaries. Eleven of the auxiliaries are now formed, and 2 more are in process of formation.

It is fondly hoped that this portion of our activities will be an accomplished fact by the time of the annual meeting.

I respectfully request officers of the district medical societies, and in particular district advisory committees, to take a strong interest, particularly at this time, in the matter of the auxiliaries, and to render them every possible assistance in the formation and extension of membership and in their various programming and other activities.

I point out that in some instances there are minor difficulties, and I ask that the advisory committees be alert, and remember that they have a veto power, upon actions of the auxiliaries that bear upon major matters in the field of, particularly, public relations and legislation.

Consequently, any major project of theirs must be approved by the local advisory committees. It is a matter of extreme importance that that be closely observed, not that malicious mistakes be made, but that mistakes due to lack of knowledge do not occur.

As with any new project, there are a few minor difficulties. There is the question of proper representation of various towns throughout a district. Occasionally, there is some suggestion of factionalism and minor matters of that type, but I see no major difficulty.

I conclude my report with the observation that not only is the Auxiliary doing everything that we fondly hoped

Committee on Finance — Dr Robert W Buck
(Middlesex South), *Chairman*

Dr Buck presented the report as printed (Appendix No 7) and moved the adoption of the first recommendation as follows

An increase of \$1500 in the salary of the Director of Medical Information and Education above that provided in your action last year by which annual increases were to amount to \$500 each year until a total salary of \$10,000 was reached. It is the opinion of the officers of the Society, the members of the original committee that chose the Director and of other representative fellows that the full salary should be paid beginning in 1949 instead of in 1952

The motion was seconded, and it was so voted

Dr Buck moved the adoption of the second recommendation as follows

I move an increase of \$1200 in the salary of the Executive Secretary, which has been requested by officers of the Society, and approved by your committee and also approved by the Executive Committee.

The motion was seconded, and it was so voted

Dr Buck then moved that the salary of the Assistant Treasurer be fixed at \$500 (no salary had been paid previously). The motion was seconded, and it was so voted

Dr Buck then moved that the Director of Medical Information and Education be provided with secretarial service at an annual cost of \$2,000. The motion was seconded, and it was so voted

Dr Buck then moved "that the increase in the budget for the Committee on Legislation be adopted, with the explanation that this increase will largely be demanded because of increased secretarial duties that will be required". The motion was seconded, and it was so voted

Dr Buck then spoke as follows

I only wish to call attention to the last paragraph and perhaps emphasize it. We have found no difficulty in using up the additional funds that have been supplied by the increase in dues. There have been so many requests and apparent real needs for the use of these funds that it becomes a little too easy to spend money. We must now realize that we have reached almost the limit of our possible expansion and that it is now up to the chairmen of all committees and to all of us to realize that we are working within our budget, but not with any great margin to spare and nobody wants to see another increase in dues or have to raise money from some other source

Dr Buck then made the motion to accept the report as a whole. The motion was seconded, and it was so voted

Committee on Industrial Health — Dr Daniel L Lynch (Norfolk), *Chairman*

Dr Lynch presented the report (Appendix No 8) as informational and moved its acceptance. The motion was seconded, and it was so voted

Advisory Subcommittee on Malpractice Insurance — Dr Carl Bearse (Norfolk), *Chairman*

Dr Bearse submitted his report (Appendix No 9) with one correction — that is, 155 suits pending in-

stead of 147. He added that during 1947 there were 64 new suits entered in courts. Dr Bearse stated that his committee had sent questionnaires to 5530 doctors, letters were sent to 49 secretaries of medical organizations and to all companies writing malpractice insurance in Massachusetts

Dr Bearse made the motion that the Council approve the recommendation concerning "listeners". The motion was seconded. Dr John Curley stated the arguments against the motion as discussed in the Executive Committee. Dr McCarthy (Norfolk) spoke in favor of the motion. Dr Dame (Franklin) spoke against the motion. Dr Allan M Butler (Suffolk) pointed out that either the doctor or the insurance company could employ "listeners" if they wished

The President stated the motion, and it was not carried by voice vote

Dr Bearse then made a motion to approve the second recommendation concerning a panel of experts. The motion was seconded. There was no discussion. On voice vote the motion was defeated

Dr Bearse then made a motion that the Council approve the third recommendation that his committee review the testimony of members and that if the testimony were found substandard, the matter would be reported to the Committee on Ethics and Discipline. The motion was duly seconded, and it was so voted

Dr Bearse then moved that the Council approve the fourth recommendation that the insurance companies be notified of the actions of the Council in these matters. The motion was seconded

Dr Kickham (Norfolk) said he believed there was no necessity for the Council to report its actions to any insurance company. On a show of hands the motion was lost

Dr Bearse then moved for acceptance of the report as a whole. This motion was seconded, and it was so voted

The Secretary called the attention of the Council to the recommendation of the Executive Committee praising the committee for the good job it had done and hoping that it would continue to act. The Secretary moved the approval of this recommendation by the Council. The motion was seconded, and it was so voted

Committee on Emergency Medical Service — Dr Reginald Fitz (Suffolk), *Chairman*

In the absence of the Chairman, the Secretary submitted the report (Appendix No 10) and stated the arguments of the Executive Committee against the recommendations of the committee concerning the make-up of the committee as proposed. The Secretary made the motion that the recommendation of the Committee on Emergency Medical Service be disapproved by the Council. This motion was seconded

ferred to the Committee on Public Health. The motion was seconded, and it was so voted.

Dr B E Barton (Norfolk) said that to further the Gallupe Plan and other purposes it is desirable to have every eligible practitioner enrolled in the Society. He said that at a pre-Council meeting of the councilors of the Norfolk District Society, the following resolution was passed: "That the Massachusetts Medical Society be informed that the Norfolk District favors placing before the Council for its consideration the matter of contacting eligible nonmembers of the Society to see if they would be interested in becoming members." Dr Barton moved acceptance of the resolution. The motion was seconded, and it was so voted.

The President recognized Dr Earle M Chapman (Suffolk), who made the following remarks:

I come before the Council as a representative of a group of earnest younger men in medicine who have met and discussed these problems that we are faced with and they have asked me to present these as their expression of their ideas on the current problems, so I should like to bring this up for consideration.

First, we believe that the health of the people served by prepayment insurance plans will be most benefited by medical care free of Government administration and control.

Secondly, we should like to call attention to the profligate waste and duplication in health programs operated by the Government in both hospital beds and personnel, as reported by the Hoover Commission. We believe that compulsory health insurance operated by the Government would result in similar inefficiencies.

Thirdly, the manner of expression of policy on the part of the American Medical Association has served to diminish public confidence in that body, to the serious concern of many of the members of the Association.

Therefore, we suggest as constructive proposals, worthy of support, the following:

First, unqualified endorsement of the principles for distribution of medical care agreed upon by the National Health Assembly in Washington, D C, in May of 1948. And specifically within that body of principles, we endorse the action of the Massachusetts Medical Society in promoting, one, the rapid expansion of voluntary medical care prepayment plans to provide more comprehensive enrollment. We appreciate that it will be necessary to use tax funds to extend such services to income groups financially unable to secure such benefits.

And secondly that benefits under these prepayment plans be expanded to provide more comprehensive coverage for illness. Implicit in this expansion should be the principle of the assumption of a portion of the initial cost of any one illness by the subscriber.

We further urge that our delegates to the American Medical Association be instructed to press for the general adoption of the above principles and proposals by the American Medical Association.

Dr Leland S McKittrick (Suffolk) was recognized and spoke as follows:

Dr Chapman was good enough to give me a copy of these suggestions and I have been thinking them over. I should like to say at the outset that I am not only sympathetic with but also enthusiastic for the thinking and the initiative that is behind these suggestions.

I am perfectly sure that, without a great deal of thought and a great deal of discussion, there are certain things in the suggestions that we would find it difficult to approve. I could not possibly approve, for example, of unqualified endorsement of the principles for the distribution of medi-

cal care agreed upon by the National Health Assembly in Washington. There are certain things that I would want to go over very carefully. But I think that the thinking behind this might well represent something that we could give careful thought to, and the suggestion I have is this:

I wonder — and I am not going to make it in the form of a motion because I do not know whether it is a proper thing to do or not, whether it would be agreeable to Dr Chapman and whether the Council would like it — but the suggestion is that this be referred to the Committee on Economics, with the request that it be given careful thought, and that they bring back and send to the Council some concrete suggestions in keeping with the thinking behind this communication.

In other words, it is about time that the Committee on Economics got to work again. I think, as a matter of fact, that we have some principles that the Council has agreed upon, which are far better than the National Assembly endorsement that is asked for here. It is possible that the Council and the Society have already proved that concrete suggestions might be brought back that the delegates could take to Atlantic City with them.

At any rate, I think it is worth a good deal of careful consideration and probably several long, hard meetings to try to come up with something. And that would be my suggestion as a possible mechanism of handling this communication.

Dr McKittrick moved that this be referred to the Committee on Medical Economics. The motion was seconded.

Dr Faxon and Dr Bagnall endorsed the substance of Dr Chapman's proposals. Dr Bagnall said he would like to have the group discussing this matter enlarged to include the Society's delegates and Dr Chapman's group. Dr Norman A Welch suggested that the matter might be one of public relations rather than economics. Dr Curley moved the following amendment to the motion: "That the matter be referred to a joint meeting of the Committees on Medical Economics and Public Relations." The motion was seconded, and it was so voted. The President called for a vote on the motion as amended. It was so voted. Dr Bagnall said that all interested parties would be invited and set the time of the meeting as Wednesday, February 9, 1949.

A motion to adjourn was made and seconded, and it was so voted at 3 00 p m.

H QUIMBY GALLUPE, *Secretary*

it would do but also the Auxiliary as a whole, as now constituted, is doing an excellent job and we expect a tremendous amount from it in the immediate future

Report of the Meeting of the House of Delegates of the American Medical Association — Dr Walter G Phippen (Essex South)

Dr Phippen made the following statement

This report is merely informational. You will find it on the last two and a half pages of the Circular of Advance Information (pages 30, 31 and 32). If there is any question anyone wishes to ask, I should be very glad to answer it.

I should like to say that your delegates to the House of Delegates would be very glad to receive any information or any criticism that you have, or to be instructed in any way you would like to have them vote. Remember, always, that they are your servants and try to act exactly as you would like to have them act.

The House of Delegates is a serious body. It consists of 175 members elected by the different constituent state societies, in addition to 1 member from each section of scientific assembly, and 1 member each from the Army, Navy and Public Health Service. The meetings are extremely well attended. The work is all conducted in a business-like way. The resolutions are presented to the House and are then handed to reference committees. These reference committees are chosen before the House sits, so that the men know on which committee they are going to serve.

At the appointed time these reference committees hold hearings at which anyone is invited to come and talk — not necessarily members of the House of Delegates, not necessarily entirely members of the American Medical Association, but anyone may come to a meeting of a reference committee and express his views.

After the reference committees have heard all the evidence they sit sometimes for long hours, sometimes well after midnight, discussing the questions that they have before them, and drawing up a report.

This report is then presented to the full House of Delegates and is open for debate, which is often lively and spirited.

I can assure you that, contrary to the belief of some people, the House of Delegates is really a representative body. You meet there people from all over the country. You may sit beside a man from Texas at breakfast and a man from Oregon at lunch, and you learn the very diversified opinions that are prevailing all over the country.

Your delegates propose to hold a meeting some weeks before the meetings of the House of Delegates so that they may discuss the problems that are of interest to you.

Dr Phippen then made a motion to accept the report. The motion was seconded, and it was so voted.

The Secretary then made a motion to accept the report of the Executive Committee as amended. The motion was seconded, and it was so voted. The Secretary then moved to recess until 2 00 p m. The motion was seconded, and it was so voted.

After the Cotting Luncheon, the Council was called to order by the President at 2 00 p m.

The Secretary stated that under unfinished business was the report of the Committee on Tax-Supported Medical Care, which had been laid on the table at the meeting of October 6, 1948.

Dr A J A Campbell (Suffolk) made a motion that this report be taken off the table. The motion was seconded, and it was so voted.

Dr Albert A Hornor (Suffolk) stated that the question of tax-supported medical care was still confused and that his committee needed more data.

He made the motion that the matter be referred back to the committee for a report at the annual meeting. The motion was seconded, and it was so voted.

The Secretary stated that under unfinished business was the matter of voluntary registration of cancer, recommended by the Committee on Cancer, which had been laid on the table at the October 6, 1948, meeting. The Secretary moved that the following motion be taken off the table.

It is therefore recommended by the Committee on Cancer that the Massachusetts Medical Society endorse the principle of voluntary registration of cancer cases, and that the Committee on Cancer be instructed to develop a system for consideration by the Council.

The motion was seconded, and it was so voted.

Dr Thomas J Anglem (Suffolk) made a motion to approve the above recommendation for the following reasons:

The nature of the disease is such that everyone accepts the fact that long-term study and statistical analysis of large groups of cases is essential, and we believe that the centralization of registration in some one area or place would definitely facilitate this type of study. At present, the cases are buried in the files of various hospitals, and anyone attempting to do a large-scale study is working against difficult odds.

Moreover, we believe that this type of registration would uncover and identify cases that are now being lost. The large number of cases that are seen by the family doctor in advanced or moderately advanced stages of the disease that are not now registered anywhere would be uncovered by this type of registration. And we also believe that anything that focuses further attention on the disease has educational value.

The motion was seconded.

Dr Charles C Lund and Dr Vlado A Getting spoke in favor of the motion. Dr Getting offered the following amendment to the motion: "That the first portion of endorsing voluntary registration be omitted and that the motion read that the 'Committee on Cancer of the Massachusetts Medical Society be authorized to make a study and present a plan to the Council for voluntary registration of Cancer'."

The motion was seconded, and it was so voted. The President then called for a vote on the motion as amended. It was so voted.

Dr Anglem moved the acceptance of the report as amended. The motion was seconded, and it was so voted.

The Secretary said that under new business Dr Root had sent a letter to the President recommending that the matter of diabetes detection among industrial groups be studied. The Secretary moved that this matter be referred to the Committee on Diabetes. The motion was seconded, and it was so voted.

The Secretary stated that he had received a letter from the Massachusetts Society of Clinical Psychologists concerning the problem of registering clinical psychologists as assistants in the practice of psychiatry. The Secretary moved that this matter be re-

ferred to the Committee on Public Health. The motion was seconded, and it was so voted.

Dr B E Barton (Norfolk) said that to further the Gallupe Plan and other purposes it is desirable to have every eligible practitioner enrolled in the Society. He said that at a pre-Council meeting of the councilors of the Norfolk District Society, the following resolution was passed: "That the Massachusetts Medical Society be informed that the Norfolk District favors placing before the Council for its consideration the matter of contacting eligible nonmembers of the Society to see if they would be interested in becoming members." Dr Barton moved acceptance of the resolution. The motion was seconded, and it was so voted.

The President recognized Dr Earle M Chapman (Suffolk), who made the following remarks:

I come before the Council as a representative of a group of earnest younger men in medicine who have met and discussed these problems that we are faced with and they have asked me to present these as their expression of their ideas on the current problems, so I should like to bring this up for consideration.

First, we believe that the health of the people served by prepayment insurance plans will be most benefited by medical care free of Government administration and control.

Secondly, we should like to call attention to the profligate waste and duplication in health programs operated by the Government in both hospital beds and personnel, as reported by the Hoover Commission. We believe that compulsory health insurance operated by the Government would result in similar inefficiencies.

Thirdly, the manner of expression of policy on the part of the American Medical Association has served to diminish public confidence in that body, to the serious concern of many of the members of the Association.

Therefore, we suggest as constructive proposals, worthy of support, the following:

First, unqualified endorsement of the principles for distribution of medical care agreed upon by the National Health Assembly in Washington, D C, in May of 1948. And specifically within that body of principles, we endorse the action of the Massachusetts Medical Society in promoting, one, the rapid expansion of voluntary medical care prepayment plans to provide more comprehensive enrollment. We appreciate that it will be necessary to use tax funds to extend such services to income groups financially unable to secure such benefits.

And secondly that benefits under these prepayment plans be expanded to provide more comprehensive coverage for illness. Implicit in this expansion should be the principle of the assumption of a portion of the initial cost of any one illness by the subscriber.

We further urge that our delegates to the American Medical Association be instructed to press for the general adoption of the above principles and proposals by the American Medical Association.

Dr Leland S McKittrick (Suffolk) was recognized and spoke as follows:

Dr Chapman was good enough to give me a copy of these suggestions and I have been thinking them over. I should like to say at the outset that I am not only sympathetic with but also enthusiastic for the thinking and the initiative that is behind these suggestions.

I am perfectly sure that, without a great deal of thought and a great deal of discussion, there are certain things in the suggestions that we would find it difficult to approve. I could not possibly approve, for example, of unqualified endorsement of the principles for the distribution of medi-

cal care agreed upon by the National Health Assembly in Washington. There are certain things that I would want to go over very carefully. But I think that the thinking behind this might well represent something that we could give careful thought to, and the suggestion I have is this:

I wonder — and I am not going to make it in the form of a motion because I do not know whether it is a proper thing to do or not, whether it would be agreeable to Dr Chapman and whether the Council would like it — but the suggestion is that this be referred to the Committee on Economics, with the request that it be given careful thought, and that they bring back and send to the Council some concrete suggestions in keeping with the thinking behind this communication.

In other words, it is about time that the Committee on Economics got to work again. I think, as a matter of fact, that we have some principles that the Council has agreed upon, which are far better than the National Assembly endorsement that is asked for here. It is possible that the Council and the Society have already proved that concrete suggestions might be brought back that the delegates could take to Atlantic City with them.

At any rate, I think it is worth a good deal of careful consideration and probably several long, hard meetings to try to come up with something. And that would be my suggestion as a possible mechanism of handling this communication.

Dr McKittrick moved that this be referred to the Committee on Medical Economics. The motion was seconded.

Dr Faxon and Dr Bagnall endorsed the substance of Dr Chapman's proposals. Dr Bagnall said he would like to have the group discussing this matter enlarged to include the Society's delegates and Dr Chapman's group. Dr Norman A Welch suggested that the matter might be one of public relations rather than economics. Dr Curlev moved the following amendment to the motion: "That the matter be referred to a joint meeting of the Committees on Medical Economics and Public Relations." The motion was seconded, and it was so voted. The President called for a vote on the motion as amended. It was so voted. Dr Bagnall said that all interested parties would be invited and set the time of the meeting as Wednesday, February 9, 1949.

A motion to adjourn was made and seconded, and it was so voted at 3 00 p m.

H QUIMBY GALLUPE, *Secretary*

APPENDIX NO 2

REPORT OF THE EXECUTIVE COMMITTEE

A meeting of the Executive Committee was called to order at 1 00 p m on January 5, 1949, by the president, Dr Daniel B Reardon. The meeting followed a luncheon at the Harvard Club. All the officers of the Society were present. The councilors of Barnstable, Berkshire and Hampshire were absent.

The Secretary explained that the time of the meeting had been changed to allow for full discussion of all questions, that the Council might have the advantage of the discussions and with the hope that, as a result, the Council meetings might be shortened and improved. There were no matters referred to the Committee by the Council.

COMMITTEE REPORTS

Committee on Membership

The Committee met on December 8, 1948, and the Secretary submitted the report, which concerned requests for resignation with remission of dues, deprivation of membership for nonpayment of dues, deprivation of membership for nonpayment of district-society dues, and deprivation of membership for nonpayment and whereabouts unknown. This part of the report was accepted by the Executive Committee.

The discussion of additional categories of membership appears in Appendix No 3.

The Secretary was assured that the Executive Committee members had considered this matter as presented by the Committee on Membership very carefully. On motion duly made and seconded, the recommendation was unanimously approved.

NEW BUSINESS

The Secretary read a telegram from Dr George F Lull, secretary of the American Medical Association, received after the St. Louis Interim Session. "Recent Interim Session House of Delegates unanimously decided to assess each member of American Medical Association \$25 00. You are requested to collect this assessment through your county units or any other way you desire. Bill association for any extra expense in connection with the collection."

The Secretary pointed out that this assessment was permissible under the new by-laws of the American Medical Association, that the purposes of the fund were explained in an editorial in the *Journal of the American Medical Association*.

citation, issue of December 11, 1948, and that the fund was needed as soon as it could be collected. Dr John J Curley, a delegate, stated that it was a real emergency because the American Medical Association had no funds and that this was the first assessment ever made.

The Secretary then asked the committee to grant him permission to collect the assessment as an agent of the American Medical Association. Upon request, the Secretary quoted the following from the by-laws of the Society: "The Executive Committee shall authorize or confirm action by the officers in emergency."

Dr Arthur W Allen stated that if the committee agreed this to be an emergency, the Secretary could be authorized to act. Dr Donald Munro then moved that the committee declare that an emergency existed in relation to the collection of the assessment for the American Medical Association. The motion was seconded and unanimously carried.

Dr Munro then moved that the Executive Committee authorize the secretary of the Massachusetts Medical Society to act as an agent of the American Medical Association in the collection of the assessment. The motion was seconded by Dr Curley and unanimously voted.

REPORTS OF COMMITTEES IN CIRCULAR OF ADVANCE INFORMATION

Committee on Public Relations

The President called the attention of the committee to page 1, lines 22 to 25, of the report and said that he would leave it to the committee whether or not that should be acted upon. Dr Munro said the paragraph should be clarified. The Secretary said he had made the suggestion to the Public Relations Committee that they recommend that Dr Conlin be permitted to attend all meetings of all committees, that he might function better in his public-relations efforts. Dr Munro admitted the permission was justified, but doubted the propriety of a blanket permission to distribute information whenever Dr Conlin deemed necessary. Dr Allen suggested that Dr Munro rewrite the paragraph. Dr MacLachlan said he thought Dr Conlin ought to have the same privilege as the Secretary and the Treasurer — in other words, to attend meetings but without a vote.

Dr Conlin said he believed such permission would enhance the effectiveness of his position. Dr John Fallon said he believed the Society had employed Dr Conlin to acquire and dispense information according to his best judgment. Dr Reginald Fitz offered the suggestion that this recommendation might necessitate a change in the by-laws.

Dr Munro moved that paragraph 3 of the report on page 1 should be amended as follows: "It was the unanimous opinion of the committee that the Director of Medical Education and Information shall be a nonvoting member of all committees of the Massachusetts Medical Society. He shall be privileged to distribute the information acquired at such meetings after written approval of the committee or its chairman and further, it is the opinion of the Executive Committee that this action, if approved, be referred to the Committee on By-laws and Council Rules." The motion was seconded, and it was so voted.

The President then asked for a discussion of the paragraph beginning on line 45 of page 2 of the report. Dr MacLachlan said that he liked the code but thought it might not coincide with the code of the American Medical Association. Dr Conlin stated that the code was a forward-looking step in hospital-staff publicity problems. The press demanded to know Who What and When. Dr Stratton's committee was satisfied with the code as it stood. Dr Curley, Dr Munro and Dr Norman A Welch said that they had heard criticisms of the press release in *The Boston Herald* from the Massachusetts General Hospital of ten days ago. Dr Charles J E Kickham agreed. Dr Joseph L Murphy said that he believed the code was a proper step. Dr Curley moved that the code be referred back to the Committee on Ethics and Discipline for their further consideration and referred back to the Executive Committee. The motion was seconded, and it was so voted unanimously.

Committee on Legislation

The President drew the attention of the Executive Committee to lines 24 to 26 on page 4 of the report. "It was voted that the President of the Society appoint annually a Committee on National Legislation after consultation with the Committee on Legislation." Drs Fallon, Munro and

Curley considered this rather confusing, and Dr Belding said he believed the Committee on Legislation felt that it would be best to have a definite subcommittee so that work could be carried out harmoniously between the two, and that the President should have the power to appoint special men for special jobs at any time.

Dr Reginald Fitz suggested that the insertion of "sub-" before the word "committee" in line 25, page 4, would clarify the matter.

It was then voted to amend the report by the insertion of the prefix "sub-" before "committee" in line 25, page 4 of the report.

The Secretary then stated that he had asked the Committee on Legislation to make the recommendation beginning on line 32, page 4, so that the Society would have a method of co-operating with the Nurses Association in the writing of any proposed changes in the nurse-practice act. On motion duly made and seconded, the recommendation was unanimously approved.

Committee on Arrangements

This informational report was accepted.

Committee on Finance

Dr Buck presented the budget as printed and said that although some recommendations might be questioned, he believed all the increases could be justified.

Dr Lawrence R Dame wanted to know if there had been an increase in the use of the Library. Drs Fallon and Curley thought that there was an increase, but did not know to what extent. Dr Buck suggested that the Library might well make an annual report to the Society concerning the activities and accomplishments. Dr Curley, a trustee, said that he would bring that recommendation before them.

Dr Buck then brought up the recommendation beginning on line 37, page 6. The Secretary said that he had made that recommendation to the Committee on Finance after consultation with, and agreement from, Drs O'Hara and Bagg, who had made the salary arrangements originally. The Secretary pointed out the value of Dr Conlin's work and the danger to the Society if he was lost. Dr Reardon agreed. Dr Curley moved that the recommendation be approved. The motion was seconded, and it was so voted.

The Secretary stated that he had made the second recommendation to the Committee because of the value of Mr Boyd's work, and the inadequacy of his present salary because of the increased cost of living, and because Mr Boyd had three dependents. Dr Curley moved approval of the recommendation. The motion was seconded, and it was so voted.

Dr William M Collins moved that recommendation 3, line 47, page 6 be approved. The motion was seconded. Dr Reardon said that the Assistant Treasurer had not had a salary and that it was justified because of the increase in the work of tax returns, which he handled. The motion was carried unanimously.

Dr Lawrence Dame moved the approval of the fourth recommendation on line 50, page 6. The motion was seconded. The Secretary and Dr Conlin stated that a secretary to assist Dr Conlin was essential. He now had the part-time use of one of the three in the office. Dr Conlin stated that he believed this small investment would get a great deal more work out of the Director of Medical Education and Information. The motion was put to a vote and carried unanimously.

Dr Buck then called attention to recommendation 5, line 1, page 7, and said that it was confusing and was not a recommendation for a full-time secretary, but indicated an increase of \$2000 over what the committee spent in 1948 and was \$1500 more than the \$5000 budget for the year 1948. He said the increase was needed for all sorts of work of the committee, a good deal of which was secretarial in nature.

Dr Reardon then ruled that no action was necessary on this in particular and would be covered by approval of the budget as a whole. Dr Curley moved approval of the report as a whole. The motion was seconded, and it was so voted.

Committee on Industrial Health

The Executive Committee accepted the report as informational.

Advisory Committee on Malpractice Insurance

Dr Reardon introduced Dr Carl Bearer, who presented the report of his committee as printed. Dr Curley asked if

the Council had not already voted against the use of "listeners." The Secretary pointed out that the Executive Committee had opposed the use of "listeners," and that the Council had upheld the objection. Dr. Maclachlan said that there was not a large enough majority of insurance companies wanting the service to justify it.

Dr. Dame said that until a need was definitely made plain, he disapproved the use of listeners. Dr. George A. Moore said that he believed it a good idea and that it would have a salutary effect on many men who feel they say things in court with no objection being raised.

Dr. Maclachlan moved that the first recommendation be disapproved. The report was seconded, and it was so voted.

Dr. Curley said that the Executive Committee had previously refused to compile a list of experts for governmental agencies, and that it might not do so for insurance companies. Dr. Welch said that the recommendation suggested that whoever submits himself as an expert is *ipso facto* accepted as such. Dr. Curley moved that the second recommendation be disapproved. The motion was seconded, and it was so voted. Dr. Curley then moved approval of the third recommendation. The motion was seconded. Dr. Munro asked if this would not make the committee act over the head of the Committee on Ethics and Discipline. Dr. Curley suggested that insurance companies might report to this committee when they would not report to the Committee on Ethics and Discipline. On a show of hands, at the request of the President, the third recommendation was approved 8 to 5. The fourth recommendation was approved without discussion.

Dr. Arthur W. Allen and Dr. Dame then praised the committee for the good job it had done and hoped it would continue to keep in action. Dr. Maclachlan then moved that since the committee had done an outstanding piece of work, it should continue for further reports of progress. The motion was seconded, and it was so voted.

Committee on Emergency Medical Service

Dr. Fitz submitted the report as printed and stated that the committee had "leaned over backward" to present the Worcester plan as fairly as possible to the Executive Committee and the Council. The committee agreed that it should be as representative as possible, and chosen on as broad a base as possible. The Secretary said that usually a committee for a special project was better if small and appointed by the President after careful selection, and that this committee was just that. Dr. Allen thought that if the recommendation was approved the new committee might select an executive committee to carry the burden. Dr. Curley moved that the recommendation be disapproved. The motion was seconded.

The Secretary said that the committee now in existence and the present plan were formed at the suggestion of the Council on Emergency Medical Service of the American Medical Association and had the approval of the Council, and said that the committee would have to confer with the Governor's committee and might best be near Boston. Dr. Harvey A. Kelly suggested that a man from each district might be added to the present committee. The President put the question, and the motion was carried.

Dr. Curley then moved that the chairmen of the eighteen district committees as now constituted be added to the present committee. The motion was seconded, and it was so voted.

Committee to Meet with the Officers of the Bay State Rehabilitation Clinic

Dr. Charles H. Bradford submitted the report as printed and assured the committee that the clinic had the approval of the Commonwealth, that the doctors and laymen behind it were outstanding and that the orthopedic surgeons were behind it.

On a motion duly made and seconded, the first three recommendations were approved without further discussion.

Dr. Maclachlan moved the approval of the fourth recommendation after the President assured the committee that if the Council approved he would appoint the same committee. The motion was seconded, and it was so voted.

Advisory Subcommittee on Medical Education

This informational report was presented as printed, by Dr. Jankelson and accepted as such by the Executive Committee.

Committee on Diabetes

Dr. Howard F. Root presented the report as printed and asked permission to add a supplementary report. The Executive Committee gave its permission. (A mimeographed copy has been sent to each councilor with this report.) Dr. Fallon moved approval of the resolution, and the motion was seconded. There were several laudatory comments on the work of the committee, the benefits to the public and the fact that the whole program was a fine example of American medicine. The motion was carried unanimously.

Subcommittee on Blue Cross-Blue Shield Problems

Dr. Charles J. E. Kickham presented the report and stated that the first recommendation (line 27, page 26) was to make permanent the position held so successfully by Dr. McKittick during the past year. On motion duly made and seconded the recommendation was approved.

Dr. Kickham said that the second recommendation had originated with the Director of Blue Shield to get new blood into the fee committees. He also said that the third recommendation follows as a result of the second, and that the word "fee" should precede the word "committees" in line 35. On motion duly made and seconded these recommendations were approved. Dr. Kickham read the next recommendation, beginning on line 44, page 26. At the suggestion of Dr. Allen it was moved and seconded that the recommendation be approved and that lines 42 to 48 inclusive not be published in the proceedings. The motion was carried.

Dr. Kickham pointed to a typographic error on line 10, page 27 "donao" should read "clarion." With this correction, the report was approved as a whole.

Committee on By-Laws and Council Rules

The report was submitted as printed with the correction of typographical errors on line 27, page 27 "by" and "rules" should be capitalized.

On motion duly made and seconded, the report was approved as a whole.

The President called for a motion to adjourn. The motion was made, seconded and so voted at 4:40 p.m.

H. QUIMBY GALLUPE, Secretary

APPENDIX NO 3

REPORT OF THE COMMITTEE ON MEMBERSHIP

The question was discussed whether there was any need for providing additional categories of membership in the Society to take care of physicians who might not be able to pay full membership dues. At a previous meeting in August, 1948, the Committee on Membership had been requested to make an investigation of this question and report their recommendations to the Executive Committee.

Four categories of physicians who might be unable to pay the full membership dues were discussed. First, medical students and hospital interns. It was believed that there was no particular advantage to these men in being full members of the Society and that the present arrangement, by which they were invited to attend all Society meetings and receive the *New England Journal of Medicine* by subscription, fully covered their needs.

Secondly, hospital residents. It was believed that very few of these men would be interested in full membership in the Society and if they were unable to pay the full dues they could apply for remission of dues on the grounds of financial hardship.

Thirdly, physicians on salaries from the Government and other agencies whose salaries are so low that payment of dues might be a hardship. It was believed that these physicians could be helped by applying for remission of dues on grounds of financial hardship.

Fourthly, physicians who are in their first year of practice and whose incomes might be limited. It was believed that these physicians definitely required the privileges of full membership in the Society and that the \$25.00 dues (amount-

ing to little more than \$2.00 a month) should be regarded by them as part of their investment in their medical careers and in fact, should be regarded as the most essential of their early medical expenses. It was believed that they could well afford \$2.00 a month in return for the valuable privileges that membership in the Society gives them and that there was no need for considering lowering membership dues for them.

Finally, the question of staggering dues from a lower level for young physicians to a higher level for older physicians, as is done by the Harvard Club, was discussed. It was believed that this would be an unwise practice since the dues of the Society represent payment for privileges received and are the same regardless of age or length of practice of the physician. The higher dues might cause more hardship to older physicians, whose incomes would be decreasing instead of increasing in later years of practice.

For these reasons, the Committee on Membership could see no need for any new categories of membership or change in the present schedule of dues. Any exceptional cases could be adequately handled under the current by-laws.

LEWIS S. PILCHER, *Chairman*

FRANCIS P. MCCARTHY
SAMUEL N. VOSE

APPENDIX NO 4

REPORT OF THE COMMITTEE ON PUBLIC RELATIONS

The meeting of the Public Relations Committee of the Massachusetts Medical Society was held at the Harvard Club at 6:00 p.m., October 27, 1948. In addition to the representatives of eleven district societies there were present: President Daniel B. Reardon, chairman of the Committee, Dr. H. Quimby Gallupe, secretary of the Massachusetts Medical Society, Dr. John F. Conlin, director of medical education and information, and Mr. Robert St. B. Boyd, executive secretary.

The report of the Secretary, as printed in the advance notice of the meeting of the Council on October 6, 1948, was accepted.

Many of the representatives of the district societies reported the programs that had been initiated in their respective districts for emergency medical coverage. It was suggested that telephone companies could be of great help in securing physicians for emergency medical care, and that chambers of commerce were very willing to help in setting up emergency medical programs, more especially for daytime coverage.

It was unanimously voted that each representative notify the Secretary, Dr. Gallupe, of the particular plan for emergency medical coverage in effect in his District.

It was the unanimous opinion of the Committee that Dr. John F. Conlin, as director of medical education and information, should be privileged to attend all committee meetings be may desire and distribute the information as he shall deem necessary.

Dr. H. A. Robinson, Norfolk South, reported to the Committee his very favorable impressions of the work of the National Physicians Committee as a result of his recent attendance at a meeting of this organization. It was his opinion that there should be more effective co-operation with the National Physicians Committee through a more widely endorsed Massachusetts branch.

Dr. John F. Conlin discussed with the Committee the problem of the relation of the physician in matters of publicity, particularly with reference to the press and radio. It was his opinion that some sort of code should be established whereby physicians could govern themselves with reference to the release of information that might be considered of public interest. He, therefore, presented to the Committee a code that was recommended by the Executive Committee of the Eye and Ear Infirmary to the Board of Physicians in Ophthalmology and Otolaryngology for their consideration, because it was felt that such a code, if accepted by these two bodies, would further hospital publicity and afford a standard that would be welcomed by individual staff members faced with publicity problems. That code is as follows:

a The doctor's name may be used with the permission of the Chief of Service and the Infirmary's Assistant Director, to publicize the work of the Infirmary where the doctor is identified as a member of the staff rather than as an individual and where the accent is on the service and not on the individual doctor.

b The doctor's name may be used in connection with an individual case with the consent of the individual doctor as well as permission as above, where the case illustrates the work of the Infirmary and the accent is on the service to the patient and not on the doctor.

c The doctor's name may be used in information about a service or a patient, with permission as in a above, where the newspapers have most of the facts and are calling the Infirmary to verify data received through other sources.

d The doctor will supply information to the Public Relations Office on cases that are of interest to the newspapers, so that this office may issue accurate and beneficial bulletins.

e The doctor will feel free to supply data on cases that illustrate the services of the Infirmary provided the patient is willing to have his name used.

f The doctors on the staff may be relieved of calls from the press by stating that all Infirmary publicity is handled through the Public Relations Office. If, however, any contact is made by a doctor on the staff with the press or radio or a nonprofessional publication, the Public Relations Office requests that they be informed immediately.

This had been revised by the Committee on Ethics and Discipline of the Massachusetts Medical Society since the meeting of the Committee on Public Relations as follows:

(Revised) The doctors on the staff should refer all calls that come to them from the press and that deal with Infirmary publicity, to the Public Relations Office, to be cleared as in a above. If any contact is made by a doctor on the staff with the press or radio or nonprofessional publication, the Public Relations Office should be informed immediately.

g The staff will keep in mind the needs of sound hospital publicity and will make suggestions to the Public Relations Office about cases or services that could be publicized.

h A staff member will be willing to be interviewed by name on a phase of the Infirmary's work if the Chief of Service approves and, if it is a newspaper interview, if the reporter is willing to submit proof before publication.

It was the unanimous opinion of the Public Relations Committee that this code, which could serve as a standard by physicians in matters of publicity, should be referred to the Committee on Ethics and Discipline for their approval.

Dr. John F. Conlin further informed the Public Relations Committee of the various activities of his office:

a He served as Chairman of the local Publicity Committee at the American Public Health Association Meeting in Boston recently.

b At the National Public Relations Conference, which is to be held at St. Louis just prior to the interim session of the House of Delegates of the American Medical Association (November 30-December 3, 1948), Dr. Conlin will address the Annual Conference of Secretaries and Editors of State Medical Associations on the use of radio in medical society Public Relations programs.

c Requests for information and for speakers on "Socialized Medicine" are increasing. There is thus urgent need for study and dissemination of information concerning basic economic factors affecting medical practice.

d Favorable progress is being made with reference to the Health Conference sponsored by the Society. An Executive Committee has been formed and will meet to organize. It is planned to bring together a large group of "consumers" and "distributors" of medical care for a two-day meeting in Boston next February.

e Attention was again called to the fact that, of the 9100 physicians in Massachusetts, only 6600 are fellows of the Society. It is felt that there is urgent need for the extension of the Gallupe Plan in various hospitals and for the intensification of efforts to make educational facilities

available to physicians desiring to qualify for membership in the Massachusetts Medical Society

Progress continues in the field of inter-professional relationship. Drs. Reardon and Conlin were recently speakers at a meeting of the Metropolitan District Dental Society.

The current status of the Anti-vivisection and Pound Law legislation was briefly reported. A special committee to study the use of animals for medical experimentation has been appointed by the general court and the governor. This commission, of which Dr. Conlin is one of the eleven members, is expected to report its findings in December, 1948.

With reference to the matter of the Health Exhibit to be sponsored by the Massachusetts Medical Society in the fall of 1949, a committee is expected to function in the immediate future with reference to this project.

Visitations by the officers of the State Society to the various Districts are reported to be of distinct benefit and should be encouraged.

There is a definite falling off in the number of complaints received concerning night calls and lack of availability of physicians for emergency medical coverage. However, there still remains much to be done by the District Societies with reference to this important matter.

The press and radio in Massachusetts have generally been favorable to the cause of high standards of medical practice and to the promotion of public health. A cross-filing system has been found to be very helpful in the assembling of news coverage and editorial attitudes of most publications. There has been a distinct increase in the activities of the District Societies to assist the State Society in its work. Also, voluntary agencies and public officials, working in the field of health, have shown an excellent willingness to co-operate with the Society in its various endeavors and programs.

The meeting adjourned at 10 00 p.m.

HAROLD R. KURTH, *Secretary*

APPENDIX NO 5

REPORT OF THE COMMITTEE ON LEGISLATION

An informal meeting was held on May 24 without organization of the committee for the 1949 session. It was voted, however, that S. L. Skvirsky, counselor from Norfolk, act as chairman until a permanent chairman could be elected.

At the meeting held on October 6, 1948, the general policies, procedures and activities of the committee were discussed and formulated. Special powers were again delegated to an executive committee of five, to be appointed by the chairman of the committee. Mr. Charles J. Dunn was again named legislative counsel. The 1949 budget was discussed and action was postponed until the next meeting.

At the November 17 meeting the following officers were elected: chairman, Solomon L. Skvirsky, Norfolk; secretary, David L. Belding, Norfolk South; and assistant secretary, Alfred L. Duncombe, Plymouth.

The 1949 budget was considered, and in view of the greater activity in national legislation it was voted to submit a budget for \$6500 to the Committee on Finance. After considerable discussion regarding the status of the Committee on National Legislation, it was voted that the president of the Society appoint annually a committee on national legislation after consultation with the Committee on Legislation, that all reports and actions of the subcommittee be cleared through the legislative committee, and that the president make such additional emergency and temporary appointments for handling national legislation as in his opinion the situation demands. The matter of probable new legislation regarding the registration of nurses came to the attention of the Committee. It was voted that the Committee recommend to the Council that the president appoint a committee of five to meet with the Massachusetts Nursing Association.

The 1949 Massachusetts legislative session will begin on January 5, 1949, and in all probability new committees in both branches of the General Court will be named at this time. It is hoped that the printed bills will be available also.

The role of the federal Government in the development and financing of social programs in the fields of health and social welfare generally is a factor of major importance.

The Eightieth Congress enacted several new health laws. They voted increased appropriations to expand many of the existing federal and state health and social welfare programs. Neither the Taft Bill (S 545) nor the Wagner-Murray-Dingell Bill (S 1320) was acted upon because it was decided that further study was necessary. This respite was made possible by the adoption of Senate Resolution 249—introduced by Senator H. Alexander Smith, of New Jersey. The resolution provided for the use of the Subcommittee on Health \$10,000 to continue its study of national health problems.

The Hoover bipartisan commission established to study and prepare plans for reorganization of the federal Government will submit its recommendations to Congress early in January. Action on the favorably reported bill to create a department of health, education and security under a head with cabinet rank was postponed until the Hoover Commission makes its report.

The officers and the following legislative councilors will constitute the executive subcommittee on legislation: William E. Browne, Suffolk; Arthur H. Riordan, Hampden; and John B. Butts, Worcester.

SOLOMON L. SKVIRSKY, *Chairman*

APPENDIX NO 6

REPORT OF THE COMMITTEE ON ARRANGEMENTS

A meeting of the Committee on Arrangements was held at 8 Fenway, November 10, 1948. Besides the members of the Committee and officers of the various scientific sections of the Society, the meeting was attended by President Dr. Daniel B. Reardon, President-Elect, Dr. Arthur W. Allen, Dr. W. Richard Ohler, of the Committee on Postgraduate Education, Dr. George R. Dunlop, of Worcester, and Mr. Robert St. B. Boyd.

Attention was called to the fact that the first committee on arrangements had been appointed February 20, 1849, and that the present committee is, therefore, the one hundredth consecutive such group to serve the Society. The only older committee is that on publications, which was established in 1825 and which has functioned since then without interruption.

The 1949 annual meeting will be held at the Memorial Auditorium in Worcester, May 24, 25 and 26. It is interesting to note that the first meeting of the Society held outside Boston was in that city—in May, 1851. Since then the Society has been the guest of the Worcester District three times in 1928, 1934 and 1939.

The formation of a three-day scientific program, which shall include at least some subjects acceptable to all members of the Society, avoiding matters that are too technical and covering for the most part problems with which the general practitioner has to deal, is not an easy matter. It requires careful, thoughtful and unhurried study, involving, as it does, the selection of speakers as well as of subjects.

In approaching the problem this year, the Committee has followed the recent custom of inviting the officers of the several sections to sit in with us and to give us suggestions toward the attainment of such a program. Their contributions have been very helpful and will form the basis of the final program.

The Committee has also received requests regarding subject matter for the program from practicing members in various parts of the Commonwealth and so far as practicable their requests will be included.

The Worcester District Society, through a committee headed by Dr. George Dunlop, is working in close co-operation with the Committee and through them it is hoped that a goodly representation of speakers from the central and western parts of Massachusetts will consent to give papers and that the hospitals in those sections will favor us with interesting exhibits. In response to several requests present plans call for more movies because of their educational value than have recently been shown.

The newly formed Woman's Auxiliary of the Massachusetts Medical Society will be responsible for entertaining the ladies, with Mrs. Charles Ayers, of Worcester, the vice-president, as chairman. As usual, the countless details of

organizing the mechanics of the convention are under the efficient direction of Mr Robert St B Boyd executive secretary of the Society. For his interest and tireless effort the Society is greatly indebted.

HAROLD G GIBBINGS *Chairman*
FRANKLIN G BALCH, JR
GORDON DONALDSON
ALBERT EHRENFRIED
JOHN W NORCROSS

APPENDIX NO 7

REPORT OF THE COMMITTEE ON FINANCE

The Committee on Finance presents its report of the expenditures of the Society during 1948. Figures for November and December are estimated, so that the total amounts are only approximate, but reasonably accurate. The budget for 1949, agreed upon by the Committee at a meeting held November 23, 1948, is also presented.

The 1949 budget exceeds that for 1948 by nearly \$56,000, representing added expenditures of more than \$10 for each member of the Society and amounting to an increase of about 65 per cent over last year. This rise is accounted for largely by the cost of membership in the Boston Medical Library (\$27,000), the contribution to the Medical Benevolent Society (\$10,000) and increases in salaries (\$11,000), all of which were authorized by vote of the Council or requested by officers of the Society or have appeared in committee budgets.

Your approval of these salary rises is invited in the following recommendations by the Committee (all of which are included in the budget).

An increase of \$1500 in the salary of the Director of Medical Information and Education above that provided in your action last year by which annual increases were to amount to \$500 each year until a total salary of \$10,000 was reached. It is the opinion of the officers of the Society, the members of the original committee that chose the Director and of other representative fellows that the full salary should be paid beginning in 1949 instead of in 1952.

An increase of \$1200 in the salary of the Executive Secretary requested by the officers of the Society and approved by the Committee.

Provision of a salary of \$500 for the Assistant Treasurer, whose duties have increased under the present situation requiring the preparation of tax returns.

Provision of secretarial service for the Director of Medical Information and Education at a cost of \$2000.

Provision of secretarial service for the Committee on Legislation, which would add \$2000 to the sum otherwise allotted this committee.

It is only proper that the attention of the Society be called to the fact that our expenses are closely approaching our estimated income in amount. If we are able to live within our budget during 1949, there will be a surplus of only \$8000 to be turned into the Building Fund. If our expenses continue to rise, provision for a larger income, presumably by a further increase in the annual dues, will have to be considered. This is desired by no one. The alternative is a conscious effort on the part of all concerned to reduce expenses wherever possible.

APPENDIX NO 8

REPORT OF THE COMMITTEE ON INDUSTRIAL HEALTH

This report is informational only. The Committee on Industrial Health is alert to the proposed development of a health service for federal employees in Boston in the near future and its probable later extension to the larger communities within the Commonwealth. In this regard your committee chairman has had several conferences with representatives of the United States Public Health Service and this committee, with Dr J J Poutas representing the Committee on Public Health and Dr John F Conlin, director of medical education and information, held a formal meeting with Dr Murphy and Dr Weiskopf, of the Public Health Service, to be informed upon the workings of the proposed health service. Dr Murphy had recently completed a survey for the organization of the health service in Boston and was preparing recommendations for its establishment, and Dr Weiskopf reported upon the operation of the service, which he directs in the United States Treasury Dept., Washington, D C.

The Health Service for Federal Employees came into being as the result of Public Law 658 favorably passed upon by the Seventy-Ninth Congress on August 8, 1946. Thus far units have been established only in Washington, D C, St Louis and New Orleans. The actual establishment and operation of a unit depends upon appropriation of the necessary funds by Congress. So far no appropriation has been made for the proposed unit in Boston, but we are advised by letter of December 10 from the medical director of the Division of Federal Employee Health, United States Public Health Service, that a recommendation for such funds is now in preparation and is to be acted upon by the next Congress.

The law emphasizes the prevention of illness but does not provide for general medical care. Specifically it provides for

Treatment of on-the-job illness and dental conditions requiring emergency attention

Pre-employment and other health examinations

Referral of employees to private physicians and dentist.

Preventive programs relating to health

It is proposed to establish a main unit in the Federal Building in Post-Office Square, staffed by qualified personnel, physicians, nurses, technicians and others associated with or supervised by the Public Health Service, adequately equipped with x-ray and other diagnostic aids and to establish six so-called satellite units in other federal agencies in Boston proper. In his recent letter the medical director of this service states "We are quite cognizant with the fact that competent and qualified professional personnel today demand and properly should receive remuneration commensurate with the duties required of them."

With the approval of Dr Reardon, president of the Massachusetts Medical Society, the Committee on Industrial Health and the representatives of the United States Public Health

Service have mutually agreed to co-operate in the development of this health service for federal employees in Boston and in the Commonwealth of Massachusetts to the end that it shall be ethical, that it will be consistent with the high ideals of industrial medicine as interpreted by the American Medical Association and the Committee, and that it will in no way conflict with the privileges of the private physician or his patient relationship but will, rather, enhance them. So far the representatives of the United States Public Health Service have been most co-operative.

APPENDIX NO 9

REPORT OF THE ADVISORY SUBCOMMITTEE ON MALPRACTICE INSURANCE

Since our previous report to the Council letters were sent to 22 insurance companies — all the companies we had reason to believe might write malpractice insurance in Massachusetts. In these letters the insurance companies were informed of the existence of this Committee and of its desire to co-operate with them. Inquiries were also made as to

Whether the Committee could help in the selection of experts to testify at trials for malpractice.

Whether insurance companies would like to have the Committee review physicians' medical testimony that may seem to be below the standard applicable to members of the Massachusetts Medical Society.

Whether "listeners" at trials were advisable and how often this might be necessary (Suggested by an insurance company).

The number of suits currently pending against members of the Massachusetts Medical Society, the number of new suits filed during 1947, and the number terminated that year.

Replies were received from all companies. 5 stated they were not writing malpractice insurance in Massachusetts. Practically all the companies writing this type of insurance, and several who do not, commended the idea of the establishment of this committee and expressed their desire to co-operate.

Eleven companies were very definite that the Committee could help in the selection of experts, one company hedged a bit, and 10 made no comment.

Eight companies stated they would be glad to avail themselves of the services of this committee. The remaining companies made no comment.

Fifteen companies replied to the question regarding "listeners", 11 companies unreservedly approved the idea, 1

company qualified its approval, 1 company questioned the value of "listeners", 2 companies said it "would seem to have some merit, but it is something which should be given further study", 7 companies made no comment.

All the companies writing malpractice insurance replied to the question regarding the number of suits. Sixty-four new suits were entered during 1947, 45 suits were terminated that year either by settlement or verdict. A total of 147 suits were pending.

To this total of 147 suits should be added 9 suits being handled by the Committee on Medical Defense of the Society, or a grand total of 156 suits outstanding.

These figures, of course, may change from day to day, but do give a good idea of the current malpractice situation as it affects the members of the Society. It is possible that some claims were settled before any suit was filed, but it is unlikely that insurance companies would pay any substantial amount unless a suit were entered in court.

At a meeting of the Committee on December 1, 1948, in view of the replies received, it was voted that the following recommendations be made to the Council:

That the Committee compile a list of "listeners" — these names to be obtained by a letter to all the district societies to be read at their meetings, asking that men desiring to be "listeners" communicate with the chairman of this committee.

On request for a "listener" by an insurance company, the company would be furnished with a list of appropriate names and the company would make its own selection and arrangements. This would mean that the "listener" would not be present as representing the Society but as being retained by the insurance company. If he appeared as "listener" for the Massachusetts Medical Society, no gratuity would be paid, this would be considered a service to the Society.

That the Committee compile a list of experts. The district societies would be asked to submit names of men who are willing to testify and their specialty. This list would be submitted to insurance companies on request. The companies would make their own selection and arrangements.

That the Committee review the testimony of members reported as being below the standard expected of members of the Society. If testimony is substantial, this fact would be reported to the Committee on Ethics and Discipline.

That insurance companies be informed of the recommendations approved by the Council.

CHARLES D. MCCANN

APPENDIX NO 10

REPORT OF THE COMMITTEE ON EMERGENCY MEDICAL SERVICE

The exact part to be played by the Massachusetts Medical Society in relation to emergency medical service for the nation is at present uncertain. One fact, however, is clear: arrangements must be made so that doctors in different parts of the Commonwealth are organized to render emergency service in case of need and according to a well thought out plan.

The present committee was appointed by the Council in June. Shortly after its appointment, Dr. N. S. Scarcello introduced to the Council, as new business, a statement from the Worcester District Medical Society, which was referred to the Committee for study.

Briefly put, the Worcester District Medical Society objects to the appointment of members of an emergency medical service committee by the Council, believing that so important a committee should be more representative and should be elected by the district societies.

From the viewpoint of operability, the Worcester District Medical Society appears to have in mind reconstruction of the Procurement and Assignment Service of World War II in its essential details. As will be recalled, during those hectic days each district society had its own procurement and assignment committee with chairman and members appointed in such fashion as the district society desired. The function of such local committees was to keep track of medical needs within their territory, determining which of its physicians could be declared available for military

service, which were essential for civilian needs, and what procedures should be adopted to meet any local medical catastrophes that might arise.

After the Procurement and Assignment Service was established by the War Manpower Commission in Washington, its chairman was appointed by the Commission, his task was to obtain information from local committees and to keep track of what was going on at the state level. This he did with the assistance of a committee appointed for the purpose by the Council.

The Worcester District Medical Society believes that a more effective operation of this general plan would result if the chairman of each local committee served on the committee of the Society and if the committee elected its chairman instead of having its chairman appointed by the Council or by an outside agency.

The present committee finds no objection to such a procedure. Therefore, the committee makes two recommendations:

The Committee on Emergency Medical Service shall be appointed by the Council. It shall consist of one representative from each district society, to be chosen in such fashion as each district society may determine, provided that he shall be chairman of the Committee on Emergency Medical Service of his district society and a member of the Council. The chairman of the committee shall be elected from its members on call by the President.

If this recommendation is adopted by the Council, the present committee recommends that it be discharged.

APPENDIX NO 11

REPORT OF THE COMMITTEE TO MEET WITH THE OFFICERS OF THE BAY STATE MEDICAL REHABILITATION CLINIC

The Committee to confer with the Bay State Medical Rehabilitation Clinic met on December 8, 1948, and studied the plans already proposed for putting the Clinic into operation. Representing the Committee, the following members were present: Drs. Reardon, Gallupe, Barr, Hermann, Clark, Bauer, Bradford and Watkins, and representing the Clinic were Dr. Augustus Thorndike and the nonmedical members George Batchelder, Henry White and Charles Hodges. A program already prepared to describe the work of the Clinic was read. It will be referred to in the report as "The program." As a result of this conference, the Committee has the following report to submit:

It has been clearly shown that a substantial number of industrial and nonindustrial accidents, as well as disabling diseases, lead to partial or permanent disability every year. These accidents and diseases cause a heavy burden of loss to the persons who suffer from them, and also the community as a whole is seriously handicapped. Immediate treatment for injuries or sicknesses is available to all through hospital centers and public and private care, but there is a great lack of co-ordinated systems of rehabilitation to carry the patient through convalescence and back to the point where a normal occupation can be resumed. To meet this lack, the Bay State Rehabilitation Clinic has made plans for the organization of a center where the services of medical and surgical consultants and physical and occupational therapists will be combined with social-service aid and with vocational-guidance counselors. By co-ordinating these related services toward the one comprehensive purpose of rehabilitation, this clinic will carry out its plan more completely and on a larger scale than could be done by any individual or private agency. It will help private physicians who may wish to refer to its services any cases under their care, and it will supplement any existing industrial or hospital clinics that may call upon its aid for rehabilitation. The directorate of this clinic is made up of men of outstanding ability, and their program has been studied with

great care. There is no doubt that the work of such a group as this is urgently needed and will be well carried out. The Committee therefore recommends

That the Massachusetts Medical Society support the Bay State Rehabilitation Clinic with a complete endorsement of its program, and offer full co-operation in helping to carry out its important aims

That the first clinic should be inaugurated in Boston, to serve eastern Massachusetts, because of the availability of consultants here and the heavy concentration of industrial groups within commuting distance

That the progress and success of this clinic be used as a guide for opening other clinics in the western part of the Commonwealth as soon as this course should seem practical

That, having discharged its purpose by rendering this report, the present committee be discontinued and replaced by a working committee to be appointed by the President for the purpose of observing the Bay State Rehabilitation Clinic and consulting with its directors and assisting and making recommendations wherever they may prove helpful as new problems are encountered

APPENDIX NO 12

REPORT OF THE ADVISORY SUBCOMMITTEE ON MEDICAL EDUCATION

The subcommittee was organized on request of Mr. John J. Desmond, Jr., commissioner of education of Massachusetts, to guide him in licensing trade schools for adjuncts to the medical profession

The Committee met on December 3, 1948, and after careful deliberations, in which the President, President-Elect and Secretary participated as *ex-officio* members, agreed to recommend minimal standards for trade schools in this State. The recommendations were communicated to Mr. Desmond in the following letter

John J. Desmond, Jr., Commissioner of Education
200 Newbury Street
Boston, Massachusetts

Dear Sir:

A meeting of the Advisory Subcommittee on Medical Education of the Massachusetts Medical Society was held to discuss the problems as outlined by you in the interview you granted the Chairman. The President, President-Elect and Secretary of the Society were present as *ex-officio* members

The subject of trade schools for training of adjuncts to the medical profession was carefully discussed. It was the consensus of all present that the technical skill required of such adjuncts can be achieved only by proper training and experience acquired in well conducted schools with a proper faculty and supervised work in a hospital. Otherwise, the students cannot become either efficient or reliable and as such may be on the one hand a danger to the public and on the other unable to get and hold positions for which they were trained and spent money and time

The Council on Medical Education of the American Medical Association has established standards for acceptable schools for medical record librarians, for physical-therapy technicians, for medical technologists and for x-ray technicians. Copies of these are included. These standards were unanimously endorsed by this subcommittee as minimal requirements for corresponding schools within this State. It was felt, however, that the admission requirements may be lowered to high school graduates. The importance of a hospital affiliation must be stressed as an absolute necessity

Schools for massage should comply with the requirements for physical therapy technicians

The subcommittee was unanimous in its opinion that no trade schools for electrolysis should be licensed in this State

We refused to take cognizance of the schools for models as not related to medicine

We are deeply appreciative of your earnest efforts to elevate the standards of the schools under your supervision and are anxious to co-operate with you further

Sincerely yours,

I. R. JANKELSON, *Chairman*
Advisory Subcommittee on Medical Education

APPENDIX NO 13

REPORT OF THE COMMITTEE ON DIABETES

The special committee on diabetes had two meetings, at which time they made plans for co-operation with the American Diabetes Association's program for diabetes detection and particularly Diabetes Week

In Massachusetts the Committee distributed to every member of the Society a small four-page bulletin entitled "How to Find and Help the Diabetic Patient in Your Community". In addition, throughout Massachusetts there were a number of radio programs on diabetes detection. Certain of the district societies, at least eight in number, made energetic efforts to carry out testing of urine of many patients in the attempt to discover the untreated diabetic patient, and in addition to obtain the co-operation of the druggists in collecting urine specimens and the co-operation of radio and newspapers in disseminating information. On December 6, 1948, a joint meeting of the Middlesex East, Middlesex South, Norfolk, Norfolk South and Suffolk district societies and the New England Diabetes Association was held in Sanders Theater, Harvard University, Cambridge. The program included eight speakers and was well attended

A list of the committees appointed in the various districts is appended

The American Diabetes Association's program for Diabetes Week regarded Diabetes Week as merely the initiation of a continuing effort to find the million undiagnosed and untreated diabetic patients in the country and to bring them under the treatment of the medical profession at as early a date as possible. In other areas of the country the steps taken have varied somewhat. In a number of states special committees on diabetes have been appointed by the state societies. In a number of states, district societies have had diabetes committees appointed. However, the main effort was made by local diabetes societies that had been in existence for a few years or were in process of organization, fifty or more in number. Their program varied somewhat, but tended to emphasize special postgraduate training for doctors and education of the lay public by way of radio, newspaper and special meetings, and, finally, diabetes detection through examination of urine or blood of large numbers of patients

In certain communities highly organized plans are in progress, as in Brookline, Massachusetts, Jacksonville, Florida, and St. Louis, Missouri. Further detection units, in co-operation with the United States Public Health Service, are planned in Wisconsin and West Virginia

At the time this report is written it is too early to give any quantitative statement about the number of people tested or the amount of publicity given. It may be stated, however, as an incidental fact, that throughout the country 1704 radio stations received a total of 22,000 copies of radio short announcements. Every state and county medical journal received a printed statement, which was sent out through the co-operation of the offices of the American Medical Association

It is the Committee's opinion that a continued effort should be made to co-operate with national and other state societies to find these diabetic patients and bring them under treatment.

The district societies with committees on diabetes are as follows

Barnstable District

Dr Henry P Hopkins (Chatham), chairman

Essex North District

Dr Robert E. Blais (handling Amesbury and Merrimack)
Dr Lincoln C. Pierce, Newburyport
Dr John J. Hartigan, Greater Lawrence

Hampden District

Dr Eoline C. Dubois (Springfield), chairman
Dr Samuel Fox, Holyoke
Dr Samuel Potsubay, Holyoke
Dr Harold J. Holleran, Westfield

Middlesex North District

Dr Augustine Conroy (Lowell), chairman
Dr George Duvin, Lowell
Dr Joseph Sweeney, Lowell
Dr Leonard Hall, Lowell
Dr Allan L. Schofield, Lowell
Dr Philip G. Berman, Lowell

Middlesex East District

Dr Milton J. Quinn (Winchester), chairman

Norfolk South District

Dr Arthur P. Sullivan, Braintree
Dr Howard S. Reid, Cohasset
Dr John R. Hopkins, Hingham
Dr Frank W. Crawford, Holbrook
Dr Alexander Young, Hull
Dr Robert L. Cook, Quincy
Dr John P. Amerena, Randolph
Dr Arsham Alemlan, East Weymouth

Worcester District

Dr George Ballantyne (Worcester), chairman

Worcester North District

Dr L. B. Thompson, Gardner
Dr Wesley Brown, Petersham
Dr Charles I. Nichols, Baldwinville
Dr M. J. Grossman, Athol
Dr James G. Simmons, Fitchburg
Dr John J. Curley, Leominster
Dr Alton B. Skelton, Winchendon
Dr Clifford Lancey, West Townsend
Dr John W. Mason, Ashburnham
Dr Beatrice Perkins, Westminster

HOWARD F. ROOT, Chairman
FRANK N. ALLAN
GEORGE BALLANTYNE
JOSEPH ROSENTHAL
JAMES L. SNEAD
JAMES H. TOWNSEND
PRISCILLA WHITE

APPENDIX NO 14

SUPPLEMENTARY REPORT OF THE COMMITTEE ON DIABETES

The report printed in the Circular of Advance Information had to be written and submitted to the Secretary within forty-eight hours after the end of Diabetes Week, December 6-12. It was necessarily a preliminary report and suffered from omissions. Since that time, further information has been obtained.

It should first be stated that no quantitative statement can be made about the results of the diabetes-detection drive, in this state or elsewhere, that will be complete because it is undoubtedly true that as a result of the efforts made and the publicity given not only in the medical societies but also by newspaper and by radio, many patients, of whom we have no records, went to doctors' offices for urine tests. Furthermore, many doctors undoubtedly carried out unrecorded tests in their offices. It is also true that in many district societies and towns we do not have a complete statement. Nevertheless, I should like to add to the previous statement the fact that in Bristol South District Dr William Mason beaded the committee that divided up their territory, each man having one town. In Fall River just under 600 persons came in for voluntary urine tests. The numbers reported from Worcester, Lawrence and Boston Board of Health, in addition to the extra tests carried out in Brookline, where a long-term detection cam-

paign has been in progress for a year, indicate that fully five or six thousand persons came for urine tests. Probably many of those who had positive urine tests have subsequently been studied by their own family doctors, to whom reports were sent, and blood tests have been done in many cases.

In Brookline the plan set up by the local board of health, with the co-operation of the United States Public Health Service, requires a blood test in every case.

Great credit is due the officers of the New England Diabetes Association, particularly Dr W. R. Obler and Dr James Townsend, for their efforts to bring about a successful program for the joint meeting of Suffolk, Norfolk, Norfolk South, Middlesex East and Middlesex South in Sanders Theater on December 6. Dr Albert Hornor acted as chairman of the committee appointed by the Boston Health League.

The campaign for diabetes detection in other parts of the United States has made a very auspicious beginning. The important point to remember is that this campaign has been initiated and carried out by doctors. It is not a drive for money. It is purely a public-service effort on the part of doctors, particularly in organized medicine, with the co-operation of public-health agencies, notably the United States Public Health Service, which has received most favorable comment and support of the press, radio and citizens. It is a campaign in preventive medicine initiated by physicians that deserves very energetic prosecution. It should be remembered as brought out on a radio broadcast here in Boston, in which Drs Daniel B. Reardon, John F. Conlin, A. J. A. Campbell and Alfred Frechette took part, that the urine test when it is positive gives a diagnostic clue not only to diabetes but also to a variety of other conditions. It is well-known that glycosuria is often a striking feature of hyperthyroidism. Glycosuria may give the clue to carcinoma, peptic ulcer and coronary-artery disease. Therefore, when this simple laboratory procedure is carried out and the results are given to the family physician and that family physician carries out a complete examination of the patient, discovery of sugar may lead to discovery of other latent conditions and the bringing to that patient of much needed treatment.

It is quite evident that the public-health and the preventive aspects of this diabetes detection drive have been recognized and accepted by newspapers quite generally throughout the country. It is true that in November a printed summary of the diabetes problem was mailed to 5000 editors of the weekly newspapers of the country. Because of their acceptance of the diabetes drive as an effort in preventive medicine by physicians, if doctors through their organized societies will recognize the opportunity presented here for medicine to take the initiative, to obtain the co-operation of public-health agencies and particularly the co-operation of industry and labor, American medicine can perform a genuine service that will win friends and put our public relations on a much better footing.

The Committee on Diabetes of the Massachusetts Medical Society recommends the adoption of the following resolution.

WHEREAS, The surveys conducted in Massachusetts starting with Diabetes Week have confirmed the high incidence of diabetes previously reported, and

WHEREAS, The interest of the public in this phase of preventive medicine was stimulated with noteworthy advantage, and

WHEREAS, The physicians of Massachusetts have shown their willingness to co-operate as individuals and through their district medical societies, and

WHEREAS, The Massachusetts Medical Society has always been noted for its leadership in preventive medicine, therefore be it

RESOLVED, That the president of the Massachusetts Medical Society be requested to appoint a committee on diabetes to follow up the activities undertaken by the Committee on Diabetes Detection, appointed in 1943, and that this committee be authorized to study and develop further activities in co-operation with private and public agencies for the welfare of the diabetic patients in the Commonwealth.

great care. There is no doubt that the work of such a group as this is urgently needed and will be well carried out. The Committee therefore recommends

That the Massachusetts Medical Society support the Bay State Rehabilitation Clinic with a complete endorsement of its program, and offer full co-operation in helping to carry out its important aims

That the first clinic should be inaugurated in Boston, to serve eastern Massachusetts, because of the availability of consultants here and the heavy concentration of industrial groups within commuting distance

That the progress and success of this clinic be used as a guide for opening other clinics in the western part of the Commonwealth as soon as this course should seem practical

That, having discharged its purpose by rendering this report, the present committee be discontinued and replaced by a working committee to be appointed by the President for the purpose of observing the Bay State Rehabilitation Clinic and consulting with its directors and assisting and making recommendations wherever they may prove helpful as new problems are encountered

APPENDIX NO 16

REPORT OF THE COMMITTEE ON COUNCIL RULES AND BY-LAWS

To provide a constant authority to which questions of procedure and by-law changes may be referred by the Council for study, this committee offers the following resolution

Resolved, That Chapter IV, Section 3, of the by-laws be, and hereby is, amended by the deletion of the "and" (in line 9, page 14) after "Finance" and by the addition under the enumeration of standing committees of the following words, "By-laws and Council Rules"

Resolved, That Chapter VII be augmented by the addition of the following

Section 16 The Committee on By-laws and Council Rules shall consist of five fellows

It shall consider all suggested changes to the rules of the Council and the by-laws of the Society

It shall submit all proposed amendments of the by-laws as provided in Chapter 9 and changes to the Council for action

(Upon the adoption of said resolution all other committees on by-laws and council rules would be replaced)

To provide continuous supervision of the problems of benevolence, the following change in the by-laws is proposed, making the existing group of fellows a standing committee

Resolved, That Chapter IV, Section 3, of the by-laws be, and hereby is, amended by the addition under enumeration of standing committees of the words "and on Benevolence."

Line 9 and line 10, page 14, would then read "Medical Defense, on Society Headquarters, on Finance on Industrial Health, on By-laws and Council Rules, and on Benevolence"

Resolved, That Chapter VII be augmented by the addition of the following

Section 17 The Committee on Benevolence shall consist of five fellows

It shall co-operate with the Massachusetts Medical Benevolent Society in giving aid to fellows of the Society who are incapacitated through no fault of their own, and to their dependents in case of need

It shall operate on an annual budget not to exceed the sum allotted by the Committee on Finance and approved by the Council

It shall remit to the Treasurer all unexpended sums at the end of each year. The Treasurer shall invest such sums in a benevolent fund to be held in reserve for future emergencies

The Committee recommends the creation of a new board to be known as the Advisory Board

This board shall consist of the five most recent past presidents of the Society

To accomplish this, the Committee offers the following resolution

Resolved, That Chapter VIII be, and hereby is, amended by the omission of the words "of trial" from the title

Present section 1 will become section 2, present section 2 will become section 3 a new section 1 will read as follows

The Advisory Board shall consist of the five most recent past presidents of the Society

It shall meet at the request of the President or the Council. The functions of the Board shall be advisory

The Committee recommends that Council Rule 3 be changed to read as follows

These rules may be suspended, changed or discontinued by a vote in the affirmative of two thirds of the councilors present

The Committee recommends that the present Council rules numbered 4, 5, 6, 7 and 8 be changed respectively to 5, 6, 7, 8 and 9, and that a new Council Rule 4 read as follows

It shall be the duty of any committee chairman, submitting a report to the Council, to be present or designate a substitute. The secretary of the Society may be designated unless special background information for informed debate is needed

The Committee recommends the following preamble to Council Rules

Rules and regulations are adopted only to promote orderly and reasonably prompt transaction of business. It is the duty of the presiding officer so to apply them that considered decisions may be reached after free and full debate. They should not be permitted to preclude discussion or subvert action

EDWARD P BAGG, *Chairman*
ELMER S BAGVALL
ALBERT A HORNOR
FRANK R OBER

APPENDIX NO 17

REPORT OF THE ADVISORY COMMITTEE TO THE WOMAN'S AUXILIARY

A meeting of the Advisory Committee to the Woman's Auxiliary to the Massachusetts Medical Society was held at 2:00 p.m. on Friday, October 29, 1948, at 8 Fenway Drs David L Belding, of Norfolk South, Milton J Quinn, of Middlesex East, and John F Conlin, of Suffolk, were present

The Committee in its discussion of a suggested program for consideration by the state auxiliary made a special effort to select fields of activity particularly suited to an organization of physicians' wives interested in promoting the objectives of the Society

Projects were proposed as follows

Organization and extension of district auxiliaries and individual membership

Assistance in supporting and publicizing action of the Society in legislative matters pertaining to medical progress and the public health—as specifically requested. Until state and national legislatures reconvene no specific recommendations can be made. It is anticipated that the Committee on Legislation of the Massachusetts Medical Society may be confronted with consideration of such matters as compulsory national health insurance, antivivisection legislation and a proposal to make animals from public pounds available for medical teaching and research, chiropractic licensing, antivaccination legislation and similar matters. The Legislative Committee of the Auxiliary will be informed of action of the Society's Committee on Legislation

Co-operation with the Massachusetts Health Conference. It is planned to conduct a week-end meeting in February to bring together about 1000 representatives of consumers and suppliers of medical care. This meeting through panels and smaller groups will study numerous phases of health in the Commonwealth and will make recommendations for improvement during the next five years

Health Exhibit in the fall of 1949. This project is designed to bring together visual aids and demonstrations of matters pertaining to health and to circulate the Exhibit through the state's population centers

National Diabetes Week, December 6-12, 1948. Co-operation with the activities of the committee of the Medical Society appointed for this purpose

Affiliation with the Massachusetts Central Health Council. This organization is composed of agencies and various groups working for the advance of the public health. Representation at its meetings would make its clearinghouse facilities on health matters available to the Auxiliary members

Encourage the formation of active local health councils. Increased effort should be made to interest the leaders of community thought and activities in matters affecting medical progress and the health of the community

Health museum. This is a "long range" project. Information will soon be available

Foster increased interest in adult health education

Activities to promote friendly relations with wives of medical students, interns and residents

APPENDIX NO 15

REPORT OF THE SUBCOMMITTEE OF THE EXECUTIVE COMMITTEE ON BLUE CROSS-BLUE SHIELD PROBLEMS

The Committee held a meeting at the Medical Library on Friday, December 10, at 4 00 p m. It has also been represented at the following meetings since the last meeting of the Executive Committee.

A meeting of the Blue Shield Central Professional Service Committee at which the past and present organizational relations between Blue Cross and Blue Shield were discussed in considerable detail.

A meeting of Blue Shield Fee Committee Chairmen at which the advisability of increasing Blue Shield's schedule of fees, income limitations and subscription rates was discussed.

A meeting of New England Blue Cross and Blue Shield Directors (trustees) and administrators, at which Dr Paul Hawley, chief executive officer of Blue Cross and Blue Shield Commissions, explained the proposals to establish a Blue Cross-Blue Shield Association and Health Service, Inc., for the purpose of facilitating the enrollment of national accounts.

A meeting of Massachusetts delegates to the American Medical Association and representatives of Blue Shield prior to the St. Louis meeting of the House of Delegates at which the proposals to establish a Blue Cross-Blue Shield Association and Health Service, Inc., were discussed in detail. In addition the Committee has attempted to be familiar with all related aspects of the subject and to keep the voting membership of the Blue Shield, Executive Committee of the Council and the members of the Society informed about Blue Cross and Blue Shield problems.

The Committee has been advised unofficially that the following action affecting Blue Cross and Blue Shield was taken at the American Medical Association Interim Session at St. Louis (November 30 to December 3, 1948). The House of Delegates approved the entire report of the Reference Committee on Medical Service and Pre-payment Insurance Plans on Wednesday, December 1, 1948. Dr L S McKittrick, of Massachusetts, was a member of this Reference Committee. An abbreviated report follows resolutions introduced by the Michigan State Medical Society and the Ohio State Medical Association approving the proposals for the establishment of a Blue Cross-Blue Shield Association and a Blue Cross-Blue Shield Health Service, Inc., were discussed for three hours on the morning of December 1. The Reference Committee report follows: "The Committee is in entire accord with the necessity and advisability of extending medical care and coverage of all classes of our population. Your Committee does not believe that sufficient factual data has been supplied to enable it to make an intelligent decision on this most important subject. Therefore, these resolutions are not approved."

A resolution introduced by Oregon called upon the American Medical Association to sever its relations with Associated Medical Care Plans and dissolve itself from any further responsibility for Associated Medical Care Plans' activities. The Reference Committee report was "Disapproved."

The Council on Medical Service introduced a supplemental report on the Associated Medical Care Plans' proposal to form a national insurance company, which contained the following recommendations to the House of Delegates: approve the formation of a national enrollment agency and disapprove the proposal for the formation of a national insurance company, approve the statement delineating the field of operation of the council and A M C P, which was presented to the Board of Trustees in December, 1946, and approved by the Board, but not approved by the A M C P Commission, recommend that A M C P make necessary changes in its Constitution and by-laws that would take A M C P out of the policy-making field and reaffirm the Council's authority to promote the voluntary prepayment plan program in America.

The Reference Committee report was "Supplemental Report of the Council on Medical Service relative to the Supplemental Report on A M C P. Proposal to form a national insurance company was carefully reviewed. Your Reference Committee recommends the adoption of the Supplemental Report with the following addition to paragraph

1 of the recommendations (Page 4) 'further development of co-ordination of and reciprocity among local plans'."

A resolution on policy reaffirming the A M A's belief in the application of the principle of medical care insurance on a voluntary basis was introduced by California. The Reference Committee made a few changes in wording, and then recommended adoption.

This subcommittee is of the opinion that rejection of the proposed Blue Cross-Blue Shield Association and Health Service, Inc., by the House of Delegates still leaves the door open to voluntary co-operation by the Blue Shield plans with a health service, incorporated, which will probably be established by Blue Cross alone. As a matter of good business it seems that such co-operation would be desirable.

The Committee is of the opinion that approval by the House of Delegates of the statement delineating the fields of operation of the Council and A M C P that was presented to the Board of Trustees in December, 1946, and approved by the Board, but not approved by the A M C P Commission, may result in disintegration of A M C P inasmuch as the primary concern of this organization is to be physical setup of plan offices and service equipment, personnel setup of plans, standardization of methods or systems of keeping actuarial data on plan experience, standardization of forms used by plans, uniformity of contracts and provisions for reciprocity among plans, and methods and mediums to be employed in selling and so forth.

There is no question that A M C P in the three years since its founding has done an outstanding job of promoting and extending the voluntary prepayment principle throughout the United States. If this organization is to be reduced to an informational bureau it is not unlikely that the initiative of its members, who, after all, know more about prepayment than any other group in organized medicine, will be seriously damaged.

A controversial aspect of the Blue Shield relation with the medical profession is the problem of fees for service. Obviously, there is bound to be some difference of opinion and at times dissatisfaction in this regard, on the part of both the Blue Shield's officials and the participating physicians. It is the opinion of the Committee that a mechanism should be established that would tie the fee committee closer to the Society. As a result of discussions with Blue Shield officials, the Committee recommends that a general chairman of Blue Shield's Committee of Fee Committee Chairmen be appointed annually by the president of the Massachusetts Medical Society, that the executive director of Blue Shield annually request the specialty sections within the Society and the specialty sections without the Society to review the composition of their respective Blue Shield fee committees, and that the executive director of Blue Shield suggest to the specialty sections a uniform method of rotating membership on Blue Shield committees.

The antitrust suits now pending in Oregon and San Diego, California, interest the Committee. It has come to our attention, however, that the Blue Shield is reviewing its policies particularly in regard to payment of nonparticipating physicians, retention of subscribers who leave the Commonwealth and sales policy toward Blue Cross.

It seems that the actions pending in Oregon and California are directed at medical-society policies rather than at medical care plan operations. Therefore the Subcommittee recommends that the Massachusetts Medical Society, through its appropriate committees, review its policies in the light of the antitrust proceedings against the Oregon State Medical Society and the San Diego County Medical Society.

The Committee wishes to advise that the Blue Shield Board of Directors has appointed Dr Charles G Hayden to the position of executive director, thus crystallizing an administrative relation that has existed for the past three years. The Committee heartily approves this strengthening of administrative responsibility.

We have been informed that Blue Shield has received many requests from participating physicians for membership in its Services. In view of the present policy of the Society such membership has not been accepted. The Committee plans to investigate this subject further and will report at a later date concerning its deliberations.

In conclusion, the Committee cannot possibly allow this occasion to pass without an expression of heartfelt apprecia-

rant No masses or organs were palpable No dorsalis pedis or posterior tibial pulsations were felt Both feet were cold The calves were not tender

The temperature was 97°F, the pulse 70, and the respirations 20 The blood pressure was 80 systolic, 60 diastolic

Examination of the blood showed a hemoglobin of 13.2 gm and a white-cell count of 10,500, with 62 per cent neutrophils, 32 per cent lymphocytes and 4 per cent monocytes Platelets were normal The urine was normal The sedimentation rate was 105 mm per minute, corrected to 0.81 mm per minute The hematocrit was 41 per cent The prothrombin time was 15 seconds (control, 15 seconds) The nonprotein nitrogen was 19 mg and the serum protein 4.63 gm per 100 cc, with an albumin-globulin ratio of 1.85 The cephalin flocculation and serum amylase were well within normal limits In the plain film of the abdomen a rather diffuse haziness suggested the presence of fluid Several slightly dilated loops of small intestine were seen in the upper abdomen No intra-abdominal calcification was visible

In the hospital there were several attacks of gaseous distention and epigastric pain They usually responded to codeine and chloral hydrate On the fourth hospital day there was a new area of hemorrhage in the skin of the neck following slight trauma, otherwise his condition remained unchanged Further laboratory examinations made in an effort to discover the cause of bleeding were not very helpful The bleeding time was four minutes, the clotting times in the first to fifth tubes were 8, 9, 10, 10 and 10 minutes, respectively A tourniquet test was negative The blood vitamin C level was 1.6 mg per 100 cc No evidence of serum at the end of forty-five minutes of liver failure could be obtained, and only 4 per cent bromsulfalein remained in the serum at the end of forty-five minutes The stools contained no blood and no undigested muscle The neutral fat was normal Soaps and other fat combinations were +++ On x-ray examination both pleural cavities contained free fluid No intrinsic lesion of the upper gastrointestinal tract could be made out by x-ray study, but there was thought to be evidence of a lobulated pressure defect against the second and third portions of the duodenal loop without definite involvement of the mucosa The diffuse ground-glass density of the abdomen remained

On the twenty-fourth hospital day edema developed in the scrotum and penis On the same day an exploratory laparotomy showed about a pint of clear straw-colored fluid The most striking finding was the ease with which all the tissues bled when handled This was especially true when the small bowel was handled There were no adhesions The pancreas was not seen but felt perfectly normal The liver and spleen also looked normal Toward the end of the operation the pa-

tient developed marked edema of the larynx, which was probably due to the trauma of the intratracheal tube, and this necessitated a tracheotomy

The immediate postoperative condition was good Several transfusions had been given during the procedure On the following day the patient suffered marked respiratory difficulty Rutin was started in an attempt to reduce capillary bleeding On the second postoperative day he was pale and breathing with difficulty He gradually became weaker The blood pressure fell to 60, and the pulse rose He died on the same day

DIFFERENTIAL DIAGNOSIS

DR WALTER BAUER I have bet ten to one that the pathologist cannot make a positive diagnosis in this case We shall see if he can

The skin lesions were never raised?

DR CHESTER M JONES That is right

DR BAUER The hemorrhagic discoloration was only in the region of the molars Is that right?

DR DANIEL S ELLIS He had some on the buccal surfaces, and also one on the tongue

DR BAUER I think it is very important to have a good description of the gums in this case, because one might want to entertain the diagnosis of monocytic leukemia However, I do not think this is the diagnosis

Nothing is said about reflexes or the neurologic findings

DR JONES They were normal

DR BAUER Can we accept the statement that this forty-nine-year-old man had no pulsations in his feet? Is this correct?

DR JONES We could not find them

DR BAUER Did the monocytes ever go any higher than 4 per cent?

DR JONES No

DR BAUER Did he exhibit an eosinophilia?

DR JONES He never had an eosinophilia

DR BAUER The smear remained essentially the same throughout the illness?

DR JONES There were no subsequent smears done

DR BAUER I assume that a bone-marrow biopsy was not done Is this correct?

DR JONES There was no biopsy of the bone marrow

DR BAUER I take it that the pleural spaces were never aspirated

DR JONES No

DR BAUER I wonder if I might ask why the surgeon kept a drainage tube in the gall bladder Did he drain it because of the alterations noted in the second and third portions of the duodenum? Was the gall bladder drained because of an acute pancreatitis? Was he treating an acute cholecystitis or trying to prevent it and thereby prevent another attack of pancreatitis? I presume that the surgeon thought the patient had pancreatitis but was unable

Assist in making the facilities of the Boston Medical Library and other deposits of medical literature more widely available to the medical profession

Study problems concerning the shortage of nurses and other matters pertaining to the nursing profession

Study conditions pertaining to the care of the aged and the chronically ill

Obtain familiarity with such problems relating to health in the community as housing, food and restaurant sanitation, industrial hygiene and school health

Study such problems relating to medical practice as the physician's hours of work, hospital staff appointments, night calls, days off, medical meetings, vocations and other matters that have an influence on the physician's family life

An interesting study might concern itself with statistical data on the budgeting of the physician's time. How much time is spent in attending patients without charge in office, clinic or hospital? How much time is spent in medical reading, giving and attending lectures, attending medical meetings and so forth?

Study of the basic economic factors affecting costs of medical care and such related problems as the differentiation between the cost of medical care rendered in the hospital and in the physician's private practice

CASE 35141

PRESENTATION OF CASE*

A forty-nine-year-old tanning-factory superintendent was admitted to the hospital because of abdominal pain.

Seven months before admission, having been previously well, the patient began to have attacks of abdominal pain. The pain, which was always located in the epigastrium just above the umbilicus, was severe, knifelike in character rather than colicky, and did not radiate. It began after breakfast and usually continued for two or three days, it was not affected by lunch or supper. There were periods of four or five days when the pain was absent. The pain was not affected by position, did not prevent sleep and kept him from work about two days of each week. X-ray films were said to show an ulcer at the duodenum, but an ulcer diet failed to improve the symptoms. Subsequently, x-ray films demonstrated the ulcer once but failed to show it another time. There was no nausea or vomiting. The bowels, previously regular, became constipated. There were no foul or foamy movements and no black or tarry stools. His weight fell from 185 to 150 pounds. He also noticed an increased tendency to easy bruising, which he had previously had. Mere rubbing of his eyelids produced a red color, which took about three days to be absorbed. Red spots also appeared on the face and neck. These were

never painful, and there was no swelling. Four months before admission he had a particularly severe attack, and an exploratory laparotomy at a community hospital revealed a considerable quantity of bloody fluid. No ulcer was seen. A drain was inserted in the gall bladder. This drained black and later green fluid and finally dried up three months later. The gall bladder was said to have been perfectly normal. The patient required one transfusion.

Following operation he continued to have attacks of abdominal pain as before. He was home for six weeks but returned to the hospital because of pain in the drainage wound. He remained in the hospital about three weeks and was discharged, two weeks before entering the Massachusetts General Hospital. During these two weeks the former pains subsided, but gas pains became more severe and constituted the chief complaint on admission. A diet eliminating fats made no difference in the pain. There was no jaundice, light stools, dark urine or chills or fever. Itching of the skin was noticed in the three months before admission.

The patient had been gassed and temporarily blinded in World War I. There were no sequelae except a chronic productive cough. He suffered some shortness of breath in recent years. Two years before admission, after an episode of sudden weakness and dizziness, he was found to have a low blood pressure and anemia. With iron and liver therapy his blood improved. After this he always noted some red spots, especially on the eyelids and other parts of the face. These were brought on by slight trauma and lasted about three days. There were no other evidences of easy bleeding.

Physical examination showed the patient to be alert and in no great discomfort. There were many excoriations over the arms, neck and upper back. There were also many 3-mm to 4-mm red blotches over the neck and face. These had an irregular outline, and were nontender and not raised. Areas of hemorrhage discolored the buccal mucosa and formed bluish, spongy swelling around the bases of the molars. Small, nontender lymph nodes were palpable in the left axilla and the groins. The heart and lungs were normal. On the abdomen there was a 12-cm scar to the left of the midline in the upper quadrant and a 6-cm scar in the right upper quad-

*Discussed May 1, 1947

ings The disease may occur at any age and in both sexes but is usually a disease of young people

I know of no other disease that would give this clinical picture Though I say I would like to make a diagnosis of periarteritis nodosa, there is not sufficient evidence in the way of clinical findings to substantiate this diagnosis The patient never had hypertension, abnormal urinary findings, neurologic abnormalities or evidence of serous-membrane involvement I well appreciate that some cases of periarteritis nodosa can affect only one organ We have seen patients who had arterial lesions, confined primarily to the pancreas, with minimal or few lesions elsewhere The initial attack of pain might be interpreted as due to periarteritis nodosa, with a saccular aneurysm in the pancreas that ruptured This would explain the free fluid in the abdominal cavity Yet he did not have pancreatitis I shall say that this man did not have periarteritis nodosa Furthermore, I do not believe that the pathologist can make a diagnosis and prove it beyond a point of doubt I think this patient had one of the diseases that Osler included in the erythema group I should be glad to answer questions and be more than happy to receive helpful suggestions

DR CASTLEMAN Were any autopsies performed in the cases that Osler described?

DR BAUER I am sorry to say that I waited until last night to read the case history, and I found my library inadequate on this point

DR JONES It was curious that one could palpate the neck and cause a hematoma, and yet a tourniquet on an arm did not produce bleeding

DR BAUER Some doctors feel very hard

DR JONES We were advised not to, so we did not

DR WYMAN RICHARDSON How about the low serum proteins?

DR BAUER I cannot explain this finding

DR JONES We had him on an adequate diet

DR BAUER He had bled from time to time and may not have been in good enough condition to regenerate proteins

DR RICHARDSON I think he may well have had something wrong with the liver

DR BAUER I agree — as part of a generalized capillary disease

A PHYSICIAN Can the abdominal pain be explained by infiltration of blood where it came in contact with the peritoneum — would that not give periodic attacks?

DR JONES The pain was very intense

DR BAUER Dr Short, you are the person who called this group of diseases to our attention What about it? Does it belong in Osler's group or not?

DR CHARLES L. SHORT I do not know

DR BAUER I think it is unfortunate that we use such ill defined terminology It is a reflection on us as much as on the pathologist

DR CASTLEMAN I have not spoken yet

DR BAUER I think you are going to talk about this group of diseases and that we will not agree on terminology

DR SHORT Is it Henoch's disease?

DR BAUER It is one of the diseases Osler included in the erythema group Whether it is Henoch's purpura or not, I do not know One can only say that the capillaries were abnormal It has been called by all sorts of names, and no one of them tells us anything about the mechanism or the etiology

DR ELLIS Do you think he had disseminated lupus erythematosus?

DR BAUER No, I do not

DR JONES His physician made a pertinent remark He wanted to know why we did not find albumin They found it when the patient was in the other hospital and at home on several urinary examinations I think he did show a + or ++ test on occasion, but the rest of the time the urine was normal

DR BAUER I shall re-emphasize one point — the description of the skin lesions and the recurrence of abdominal pain is classic for this disease, it fits it to a "T" as far as I am concerned

CLINICAL DIAGNOSIS

Acute disseminated lupus erythematosus

DR BAUER'S DIAGNOSIS

Osler's disease—"Erythema group of skin diseases with visceral manifestations"

ANATOMICAL DIAGNOSES

Primary systemic amyloidosis, involving myocardium, cardiac valves, lungs, spleen, lymph nodes and blood vessels

Purpuric hemorrhages of skin, intestines and peritoneum, severe

Cardiac hypertrophy and dilatation

Renal infarcts, recent, left

PATHOLOGICAL DISCUSSION

DR CASTLEMAN Our findings on examination of the abdominal cavity were almost the same as those at exploration There were subserosal hemorrhages in the wall of the small bowel, as well as submucosal hemorrhages throughout the entire gastrointestinal tract The spleen and liver looked perfectly normal, as did the pancreas The kidneys were perfectly normal in size and appearance except for a few, small, recent infarcts in the left kidney The heart was enlarged, weighing 450 gm, and on the valves were small white spots, which seem like artifacts on this photograph of the aortic valve (Fig 1)

to establish the diagnosis at the time of the exploration Is this correct?

DR JONES Yes

DR BAUER I do not believe that he had pancreatitis, but I may be wrong

May we see the films? They describe a diffuse ground-glass appearance, which is evidently due to fluid

DR TOUFIC KALIL This shows the ground-glass appearance and the separation of the loops of small bowel consistent with fluid There is fluid in both pleural spaces going into the fissures

DR BAUER This patient never had pleurisy?

DR JONES No

DR BAUER And no pericardial friction rub?

DR JONES No

DR KALIL This is the gastrointestinal series There is a pressure defect on a loop of the duodenum The nodularity described is present here in the second and third portions

DR BAUER How would you interpret the distortion?

DR KALIL It is perhaps due to increase in size of the pancreas The mucosa of the duodenal loop is all right

DR BAUER That neither helps me nor disturbs me The pancreatic enzymes were normal

The abdominal fluid and the edema of the scrotum and penis can be explained on the basis of the hypoproteinemia I wonder why he was explored Was it because of an attack of pain or other change in clinical course, or is it unfair to ask?

DR JONES No He continued to have attacks of pain, without elevation of temperature, pulse or respirations The pain was severe and required opiates There was no rigidity or tenderness at the time of the attack of pain The pain was always in the same place—in the midepigastrium and went through to the back

DR BAUER Is it known whether he had fever or leukocytosis in the first hospital?

DR JONES My impression is that he had no fever

DR BAUER The other interesting finding at operation was the ease with which the tissues bled when handled Was there hemorrhage in the serosa, or was bleeding observed in all tissues of the abdomen?

DR JONES There were several serosal hemorrhages when the abdomen was opened and not due to handling

DR BAUER Did they appear also on handling?

DR BENJAMIN CASTLEMAN Dr Richard H Sweet said that when he elevated a loop of small bowel there was diffuse oozing over the surface of the small bowel

DR BAUER That is the whole small bowel?

DR CASTLEMAN In spots, oozing here and there

DR BAUER I shall take that for what it is worth The first thing I wondered about as I read the history was whether or not there was any likelihood of benzol poisoning since he had worked in a tannery and may have been exposed to benzol However, we do not know the kind of tannery or whether benzol was used Because of his occupation this diagnosis should be considered, however, as one reviews the history one sees little reason for entertaining this possibility

We are dealing with a man forty-nine years of age, who exhibited three findings we must account for The fourth, the absence of pulsations in the feet, may not have been related to the primary disease I wish the pulsations had been felt because the other findings—recurrent purpura lasting only a few days and attacks of abdominal pain—are consistent with a diagnosis of purpura The abdominal pain lasted only a few days at any one time The abdomen was opened and contained free bloody fluid When confronted with a patient with symptoms suggesting diffuse vascular disease, in this case the capillaries, we entertain the diagnosis of periarteritis nodosa However, there is very little to substantiate this diagnosis He never had fever or a leukocytosis In fact, there was very little to suggest the presence of periarteritis nodosa except recurrent attacks of abdominal pain He did have free bleeding in the abdominal cavity on one occasion, and one might say it was due to rupture of a saccular aneurysm of the type seen in people with periarteritis nodosa At the second operation it was observed that all tissues bled very easily when handled This finding is not easily explained on the basis of periarteritis nodosa or on the basis of related or so-called "group disease" I hate to talk about "group disease" because the term can be used as a catch-all We do not know too much about the pathogenesis of "group disease" (rheumatoid arthritis, rheumatic fever, disseminated lupus, dermatomyositis, periarteritis nodosa and scleroderma) I think this man had the disease described by Osler, Henoch and Schönlein He falls in the group that Osler^{1,2} spoke of as the erythema group Erythema multiforme exudativum and Henoch's purpura are included in this group, but, as Osler said, the clinical manifestations of patients included in the erythema group vary greatly, particularly the cutaneous lesions This term, however, is merely a blanket term and can cover a multitude of sins These people give a history not unlike that of this patient and may have arterial symptoms in addition They are very apt to have bleeding into the gastrointestinal tract and may give a history of repeated bloody stools This patient evidently never had the latter, however, I do not believe that the absence of this finding should disturb us, nor should the absence of arterial find-

stains. The note is made in a number of articles that the iodine stain is negative and that the Congo red is positive. That was true here. The involvement of the endocardium has been described a number of times and was very characteristic in this case.^{3,4} I believe this is the first case in which we have seen amyloid involvement of the cardiac valves.

DR BAUER: I should still like to take exception. As yet we cannot say that amyloid disease is a complication of rheumatoid arthritis. It may be due to the same mechanism responsible for rheumatoid arthritis.

I do not think that you have necessarily proved that we are dealing with primary amyloidosis in

DR CASTLEMAN: Yes. As yet we have not found a better answer. I suppose the cases that Osler described were not associated with amyloid.

DR BAUER: I wish we knew the autopsy findings in such cases. It may be that people with primary

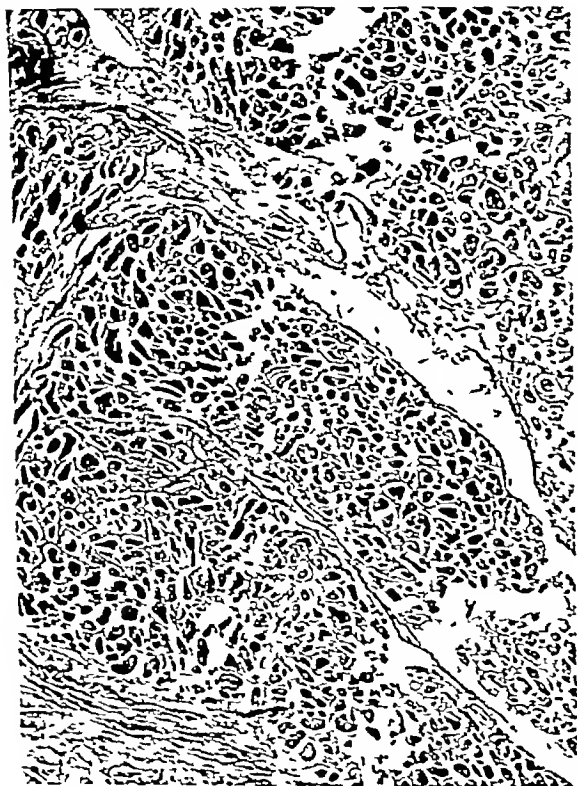

FIGURE 3 Amyloidosis of the Myocardium

this case, although there is an increasing amount of evidence that patients with diffuse vascular disease are prone to have amyloid disease.

DR CASTLEMAN: It may be true that amyloid associated with rheumatoid arthritis is all primary, but its distribution is similar to the secondary type. Certainly, the particular anatomic findings in this case are what have been seen in a large number of cases.

DR BAUER: In what has been called primary amyloid disease?

FIGURE 4 Photomicrograph of the Intestine Showing Amyloidosis of the Walls of the Submucosal Blood Vessels Surrounded by Hemorrhage

amyloidosis initially have primary vascular disease. However, this is a guess. We ought to look up the literature and see if autopsy of long-observed cases of so-called Osler's disease showed primary amyloidosis.

DR CASTLEMAN: But until we find out what the primary disease is we have to place this case in the so-called primary atypical amyloidosis group.

This is a slide of the mitral valve (Fig 2), and it shows exactly the same granules, some extending up on to the auricular wall where there were a few, small, submucosal hemorrhages and going down along the chordae tendineae, which were not, however, thickened or involved with an old process. Similar granules were found on the other valves. When we first looked at these on gross examination we thought they were similar to those seen in lupus erythematosus. The granules, however, were not

infection, rheumatoid arthritis and a few other conditions. In this type the amyloid infiltration affects almost always the liver, spleen and kidneys. Then there is the so-called primary systemic amyloid disease in which no definite primary disease can be observed anatomically. In this type the amyloid infiltration very rarely affects the liver, spleen and kidney but may affect the heart and lungs primarily, often with diffuse involvement of the vessels throughout the body. That was true in this case. The most marked involvement was in the heart and in the lungs and in the vessels throughout the body. There was a little infiltration of the spleen, which has been reported in so-called primary systemic amyloidosis. It was present, as one can see, throughout the submucosa of the intestine, and these patients very often have hemorrhages. In

FIGURE 1 Aortic Cusps, Showing Amyloid Deposits

so large as those seen in Libman-Sachs endocarditis and were more numerous.

This is a microscopical slide of one of these valves showing the amorphous, very pale-pink appearance. A Congo-red stain of the valve demonstrates that all the material on the cusps is amyloid. The endothelium itself is perfectly normal. It is interesting that amyloid stains of the liver and kidney were negative. Here is a section of lung showing amyloid infiltration of the walls of the small vessels. It is interesting that the usual iodine stain for amyloid was negative, but the Congo-red stain was positive. The heart muscle was extensively involved with amyloid (Fig 3). The cause of the hemorrhages is well seen in the section of the small intestine (Fig 4). Here is the normal mucosa, here is a submucosal hemorrhage and in it are all these small arteries extensively infiltrated with amyloid. There is diffuse amyloidosis of the arteries throughout. This case, therefore, is characteristic of the so-called primary systemic amyloidosis, not the secondary type.

DR. BAUER: How can you prove that it was primary amyloidosis and not due to another disease?

DR. CASTLEMAN: There are two main types of amyloid disease. One that we all know about is the secondary type of amyloidosis due to chronic

FIGURE 2 Mitral Valve, Showing Amyloid Deposits Extending over the Endocardium and Chordae Tendineae

the cases of primary systemic amyloid disease described in the literature, about 40 per cent are prone to bruise easily, probably owing to the fact that the amyloid infiltration of the vessels makes the vessels more vulnerable to trauma.³ I think one can argue the point and say that this is not a primary disease but is secondary to a disease that we cannot recognize anatomically. The amyloid distribution, however, is quite different from the so-called secondary amyloid disease. Another thing that is common in the primary form is that this type of amyloid does not always take up the usual amyloid

150 mg, total protein 7.11 gm, albumin 5.06 gm and globulin 2.05 gm per 100 cc. The patient grew progressively weaker despite frequent transfusions and intravenous fluids. He vomited at any attempt to eat and, although perfectly oriented, was drowsy much of the time. Hematuria and pyuria persisted. On the thirty-eighth hospital day the nonprotein nitrogen was 101 mg per 100 cc. Two days later he took a marked turn for the worse, with bleeding at all orifices. On the following day he died.

DIFFERENTIAL DIAGNOSIS

DR WALTER BAUER: If this man had difficulty keeping his food down for one year the weight loss could be accounted for on the basis of an inadequate caloric intake.

One would also like to know whether the gastrointestinal symptoms twenty-five years previously and those experienced during the four weeks prior to entry were causally related.

I assume that the diastolic murmur heard along the left border of the sternum was transmitted from the aortic area, although it is of interest that the examiner described both a blowing diastolic murmur and a Grade I whine.

I assume that the specific gravity of 1.015 is the highest recorded.

DR TRACY B. MALLORY: One specific gravity was 1.022, and the others ranged from 1.010 to 1.015. Someone put down a question mark against the 1.022 figure, however.

DR BAUER: I shall assume that the specific gravity of 1.015 represented the ability of the kidneys to concentrate.

Was there any increase in cells in the spinal fluid? Was the spinal-fluid protein increased?

DR MALLORY: The protein is recorded as 38 mg per 100 cc by the electrophoretic method and 42 by the old method.

DR BAUER: There was no mention of cells?

DR MALLORY: Yes, I see a note saying that there were 3 cells per cubic millimeter.

DR BAUER: Are there any x-ray films of the knee?

DR STANLEY M. WYMAN: No. The chest films show an apparently normal upper lung. The heart shadow is increased in transverse diameter, with prominence of the apical portion, probably representing an enlarged left ventricle. The aorta is prominent in the ascending portion and shows a suggestion of bulging but no calcification in this portion of the aorta or elsewhere in its thoracic course.

DR BAUER: Would you care to say anything further about the aortitis?

DR WYMAN: It certainly is suggestive of aortitis. Examination of the stomach shows a crater on the lesser curvature at the angle. An additional finding not noted in the original record is a deformed duodenal cap, which although present, is not well

demonstrated in this film. There is a suggestion of a filling defect in the prepyloric region, which is better seen at the examination done seventeen days later.

DR BAUER: A prepyloric crater as well as one on the lesser curvature?

DR WYMAN: It is suggestive.

DR BAUER: Nothing is said about that in the abstract.

DR WYMAN: No. These spot films show the decrease in size of the crater on the lesser curvature. The next two films selected from the pyelogram examination are not satisfactory for fine detail, but they show excretion of dye in fairly good concentration without gross distortion or dilatation.

DR BAUER: Would you say that the patient excreted the normal amount of dye?

DR WYMAN: I think he did well for a man of seventy-five.

DR BAUER: With a specific gravity of 1.015?

DR WYMAN: Very well indeed.

The film of the skull shows no demonstrable bone disease. These films of the long bones, the lower legs and forearms reveal no definite bone destruction. The joint spaces, the wrists and the ankles appear essentially normal.

DR BAUER: The question is, How many diagnoses should one make? Can all the findings be explained on the basis of one disease? I do not believe so. I think there can be no doubt that this man had multiple myeloma. The evidence for that is clear-cut and certainly adequate. It is reported that the electrophoretic studies failed to reveal Bence-Jones protein in the serum. This, however, has been true of other cases of multiple myeloma. Likewise, a hyperproteinemia and a hyperglobulinemia are not always present.* I think that this man probably had a complication seen in multiple myeloma—namely, amyloidosis. There are, of course, three kinds of amyloidosis: primary amyloidosis, amyloidosis associated with multiple myeloma and secondary amyloidosis. Visceral involvement is much less frequent in the first two, and the staining reactions for amyloid are variable and atypical. It is also of interest that in most cases of primary amyloidosis in which the total serum proteins have been determined they have been found to be essentially normal.* In amyloidosis associated with multiple myeloma Bence-Jones proteinuria is present in only about half the cases. To establish the exact incidence of primary amyloidosis one must suspect and if possible rule out myeloma in all cases of amyloidosis in which no obvious cause is found.

This man had a positive blood Hinton test, spinal-fluid abnormalities, enlargement of the left ventricle, evidence of aortic-valve incompetence and enlargement of the ascending portion of the aorta. Therefore, I would like to make the additional

*Done by the Howe technic.

CASE 35142

PRESENTATION OF CASE

A seventy-five-year-old Portuguese laborer was admitted to the hospital because of epigastric pain, anorexia and loss of weight

The patient had quit work one year before entry because of weakness, but stated that he had been well up until about two months before admission. His weight had fallen from 154 to 127 pounds. At the same time he had painful, swollen knees, but this complaint had disappeared. Three or four weeks before admission he began to experience intermittent, nonradiating, "burning" pain in the middle and left epigastrium, which occurred half an hour to one hour after meals. The pain was very sharp for ten or fifteen minutes and then wore off. Occasionally, the pain reappeared between meals. Milk and food seemed to relieve it for a while, as did belching. Sometimes he vomited a small amount with relief. There were no changes in bowel habit, and he did not notice the color of the stool. There was no hemoptysis. There was no jaundice, distention, dysphagia or prominent genitourinary symptoms. There had been recent mild ankle edema. A physician had given him pills and a white liquid for the pain, but these gave no relief. Diet during the present illness had consisted of tea, toast, soups and juices.

About twenty-five years before entry he had suffered episodes of epigastric pain which he could not clearly describe. He continued to work, and eventually these wore off without medication. Several years later he underwent an appendectomy. He denied the symptoms or treatment for syphilis or gonorrhea.

Physical examination revealed a pleasant, elderly man, showing signs of weight loss. There was no jaundice. There was a cataract in the left eye. There were a few, shotty, firm lymph nodes in the axillas, especially on the right. There were prominent inguinal chains bilaterally. The lungs were clear. The heart was boot-shaped, with the point of maximal impulse at about the midclavicular line. There were occasional premature beats, and the aortic second sound was greater than the pulmonary. There was a Grade I, blowing diastolic murmur loudest in the aortic area, a Grade I whine in diastole along the upper left sternal border, and a Grade II systolic murmur heard loudest at the apex but also heard in the axilla and at the base. The abdomen was flat, with normal peristalsis. There was an appendectomy scar in the right lower quadrant. There were no palpable masses or tenderness. The liver edge was palpated one fingerbreadth below the right costal margin on inspiration and was prominent across the epigastrium. There was a + ankle edema.

The temperature was 99°F, the pulse 96, and the respirations 18. The blood pressure was 146 systolic, 70 diastolic.

The urine had a specific gravity of 1.015 and gave a +++ test for albumin, and the sediment contained a few white cells and a rare hyaline cast. Examination of the blood disclosed a red-cell count of 2,570,000, with a hemoglobin of 7.5 gm, and a white-cell count of 17,000, with 27 per cent neutrophils, 67 per cent large lymphocytes and 4 per cent monocytes. Anisocytosis and hypochromia were noted. The stools gave a ++ guaiac reaction. The blood Hinton test was positive. The serum protein was 6.20 gm per 100 cc, with an albumin of 3.86 and a globulin of 2.34 gm (albumin-globulin ratio of 1.7). The nonprotein nitrogen was 27 mg, phosphorus 3.7 mg, and alkaline phosphatase 3.5 units per 100 cc. The prothrombin time was 24 seconds (normal, 16 seconds), the cephalin flocculation test was negative in twenty-four and forty-eight hours. A gastric aspiration showed free hydrochloric acid.

The patient's condition remained essentially unchanged. A gastrointestinal series revealed a grossly benign ulcer crater, 1.5 cm in diameter, approximately 1 cm beyond the lesser curvature of the stomach. A roentgenogram of the chest showed a heart enlarged in the region of the left ventricle. The aorta was somewhat widened, particularly in the ascending portion. On the fourth hospital day urine gave a ++++ test for albumin, and the sediment contained many red cells, with an occasional white cell and hyaline cast. A blood smear showed 8 per cent plasma cells, and a subsequent sternal-bone-marrow aspiration disclosed a marked diminution of myelopoiesis and erythropoiesis. About 80 per cent of the cells were mature plasma cells, with a few blast forms and binucleated plasma cells. Bence-Jones protein was found to be abundant in the urine. Roentgenograms of the skull, forearms, wrists and hands showed no evidence of bony disease. On intravenous pyelogram the kidneys excreted the dye promptly and outlined nondilated calyces, pelves and ureters. A serum protein electrophoretic separation produced a normal pattern, indicating the absence of Bence-Jones protein in the serum. The spinal-fluid gold-sol curve was 000034+211. A urine culture showed colon bacilli and a few nonhemolytic streptococci. On the eleventh hospital day the patient stated that he no longer had epigastric pain but that he did feel weak "all over." Five days later the white-cell count was 47,800, with 22 per cent neutrophils, 44 per cent large lymphocytes and 34 per cent small plasma cells. On the nineteenth hospital day a gastrointestinal series showed that the gastric ulcer had decreased considerably in size. The stools became black and gave a ++++ guaiac reaction. The blood calcium was 10.6 mg, phosphorus 9.2 mg, phosphatase 3 units, nonprotein nitrogen

150 mg, total protein 7.11 gm, albumin 5.06 gm and globulin 2.05 gm per 100 cc. The patient grew progressively weaker despite frequent transfusions and intravenous fluids. He vomited at any attempt to eat and, although perfectly oriented, was drowsy much of the time. Hematuria and pyuria persisted. On the thirty-eighth hospital day the nonprotein nitrogen was 101 mg per 100 cc. Two days later he took a marked turn for the worse, with bleeding at all orifices. On the following day he died.

DIFFERENTIAL DIAGNOSIS

DR WALTER BAUER: If this man had difficulty keeping his food down for one year the weight loss could be accounted for on the basis of an inadequate caloric intake.

One would also like to know whether the gastrointestinal symptoms twenty-five years previously and those experienced during the four weeks prior to entry were causally related.

I assume that the diastolic murmur heard along the left border of the sternum was transmitted from the aortic area, although it is of interest that the examiner described both a blowing diastolic murmur and a Grade I whine.

I assume that the specific gravity of 1.015 is the highest recorded.

DR TRACY B. MALLORY: One specific gravity was 1.022, and the others ranged from 1.010 to 1.015. Someone put down a question mark against the 1.022 figure, however.

DR BAUER: I shall assume that the specific gravity of 1.015 represented the ability of the kidneys to concentrate.

Was there any increase in cells in the spinal fluid? Was the spinal-fluid protein increased?

DR MALLORY: The protein is recorded as 38 mg per 100 cc by the electrophoretic method and 42 by the old method.

DR BAUER: There was no mention of cells?

DR MALLORY: Yes, I see a note saying that there were 3 cells per cubic millimeter.

DR BAUER: Are there any x-ray films of the knee?

DR STANLEY M. WYMAN: No. The chest films show an apparently normal upper lung. The heart shadow is increased in transverse diameter, with prominence of the apical portion, probably representing an enlarged left ventricle. The aorta is prominent in the ascending portion and shows a suggestion of bulging but no calcification in this portion of the aorta or elsewhere in its thoracic course.

DR BAUER: Would you care to say anything further about the aortitis?

DR WYMAN: It certainly is suggestive of aortitis. Examination of the stomach shows a crater on the lesser curvature at the angle. An additional finding not noted in the original record is a deformed duodenal cap, which although present, is not well

demonstrated in this film. There is a suggestion of a filling defect in the prepyloric region, which is better seen at the examination done seventeen days later.

DR BAUER: A prepyloric crater as well as one on the lesser curvature?

DR WYMAN: It is suggestive.

DR BAUER: Nothing is said about that in the abstract.

DR WYMAN: No. These spot films show the decrease in size of the crater on the lesser curvature. The next two films selected from the pvelogram examination are not satisfactory for fine detail, but they show excretion of dye in fairly good concentration without gross distortion or dilatation.

DR BAUER: Would you say that the patient excreted the normal amount of dye?

DR WYMAN: I think he did well for a man of seventy-five.

DR BAUER: With a specific gravity of 1.015?

DR WYMAN: Very well indeed.

The film of the skull shows no demonstrable bone disease. These films of the long bones, the lower legs and forearms reveal no definite bone destruction. The joint spaces, the wrists and the ankles appear essentially normal.

DR BAUER: The question is, How many diagnoses should one make? Can all the findings be explained on the basis of one disease? I do not believe so. I think there can be no doubt that this man had multiple myeloma. The evidence for that is clear-cut and certainly adequate. It is reported that the electrophoretic studies failed to reveal Bence-Jones protein in the serum. This, however, has been true of other cases of multiple myeloma. Likewise, a hyperproteinemia and a hyperglobulinemia are not always present.* I think that this man probably had a complication seen in multiple myeloma—namely, amyloidosis. There are, of course, three kinds of amyloidosis: primary amyloidosis, amyloidosis associated with multiple myeloma and secondary amyloidosis. Visceral involvement is much less frequent in the first two, and the staining reactions for amyloid are variable and atypical. It is also of interest that in most cases of primary amyloidosis in which the total serum proteins have been determined they have been found to be essentially normal.* In amyloidosis associated with multiple myeloma Bence-Jones proteinuria is present in only about half the cases. To establish the exact incidence of primary amyloidosis one must suspect and if possible rule out myeloma in all cases of amyloidosis in which no obvious cause is found.

This man had a positive blood Hinton test, spinal-fluid abnormalities, enlargement of the left ventricle, evidence of aortic-valve incompetence and enlargement of the ascending portion of the aorta. Therefore, I would like to make the additional

*Done by the Howe technique.

CASE 35142

PRESENTATION OF CASE

A seventy-five-year-old Portuguese laborer was admitted to the hospital because of epigastric pain, anorexia and loss of weight

The patient had quit work one year before entry because of weakness, but stated that he had been well up until about two months before admission. His weight had fallen from 154 to 127 pounds. At the same time he had painful, swollen knees, but this complaint had disappeared. Three or four weeks before admission he began to experience intermittent, nonradiating, "burning" pain in the middle and left epigastrium, which occurred half an hour to one hour after meals. The pain was very sharp for ten or fifteen minutes and then wore off. Occasionally, the pain reappeared between meals. Milk and food seemed to relieve it for a while, as did belching. Sometimes he vomited a small amount with relief. There were no changes in bowel habit, and he did not notice the color of the stool. There was no hemoptysis. There was no jaundice, distention, dysphagia or prominent genitourinary symptoms. There had been recent mild ankle edema. A physician had given him pills and a white liquid for the pain, but these gave no relief. Diet during the present illness had consisted of tea, toast, soups and juices.

About twenty-five years before entry he had suffered episodes of epigastric pain, which he could not clearly describe. He continued to work, and eventually these wore off without medication. Several years later he underwent an appendectomy. He denied the symptoms or treatment for syphilis or gonorrhea.

Physical examination revealed a pleasant, elderly man, showing signs of weight loss. There was no jaundice. There was a cataract in the left eye. There were a few, shotty, firm lymph nodes in the axillas, especially on the right. There were prominent inguinal chains bilaterally. The lungs were clear. The heart was boot-shaped, with the point of maximal impulse at about the midclavicular line. There were occasional premature beats, and the aortic second sound was greater than the pulmonary. There was a Grade I, blowing diastolic murmur loudest in the aortic area, a Grade I whine in diastole along the upper left sternal border, and a Grade II systolic murmur heard loudest at the apex but also heard in the axilla and at the base. The abdomen was flat, with normal peristalsis. There was an appendectomy scar in the right lower quadrant. There were no palpable masses or tenderness. The liver edge was palpated one fingerbreadth below the right costal margin on inspiration and was prominent across the epigastrium. There was a + ankle edema.

The temperature was 99°F, the pulse 96, and the respirations 18. The blood pressure was 146 systolic, 70 diastolic.

The urine had a specific gravity of 1.015 and gave a +++ test for albumin, and the sediment contained a few white cells and a rare hyaline cast. Examination of the blood disclosed a red-cell count of 2,570,000, with a hemoglobin of 7.5 gm, and a white-cell count of 17,000, with 27 per cent neutrophils, 67 per cent large lymphocytes and 4 per cent monocytes. Anisocytosis and hypochromia were noted. The stools gave a ++ guaiac reaction. The blood Hinton test was positive. The serum protein was 6.20 gm per 100 cc, with an albumin of 3.86 and a globulin of 2.34 gm (albumin-globulin ratio of 1.7). The nonprotein nitrogen was 27 mg, phosphorus 3.7 mg, and alkaline phosphatase 3.5 units per 100 cc. The prothrombin time was 24 seconds (normal, 16 seconds), the cephalin flocculation test was negative in twenty-four and forty-eight hours. A gastric aspiration showed free hydrochloric acid.

The patient's condition remained essentially unchanged. A gastrointestinal series revealed a grossly benign ulcer crater, 1.5 cm in diameter, approximately 1 cm beyond the lesser curvature of the stomach. A roentgenogram of the chest showed a heart enlarged in the region of the left ventricle. The aorta was somewhat widened, particularly in the ascending portion. On the fourth hospital day urine gave a ++++ test for albumin, and the sediment contained many red cells, with an occasional white cell and hyaline cast. A blood smear showed 8 per cent plasma cells, and a subsequent sternal-bone-marrow aspiration disclosed a marked diminution of myelopoiesis and erythropoiesis. About 80 per cent of the cells were mature plasma cells, with a few blast forms and binucleated plasma cells. Bence-Jones protein was found to be abundant in the urine. Roentgenograms of the skull, forearms, wrists and hands showed no evidence of bony disease. On intravenous pyelogram the kidneys excreted the dye promptly and outlined nondilated calyces, pelves and ureters. A serum protein electrophoretic separation produced a normal pattern, indicating the absence of Bence-Jones protein in the serum. The spinal-fluid gold-sol curve was 0000344211. A urine culture showed colon bacilli and a few nonhemolytic streptococci. On the eleventh hospital day the patient stated that he no longer had epigastric pain but that he did feel weak "all over." Five days later the white-cell count was 47,800, with 22 per cent neutrophils, 44 per cent large lymphocytes and 34 per cent small plasma cells. On the nineteenth hospital day a gastrointestinal series showed that the gastric ulcer had decreased considerably in size. The stools became black and gave a ++++ guaiac reaction. The blood calcium was 10.6 mg, phosphorus 9.2 mg, phosphatase 3 units, nonprotein nitrogen

et al² They observed 4 cases with normal total serum protein levels with hyperglobulinemia, 11 cases with apparently normal distribution of serum protein fractions and 1 with marked hypoproteinemia (4.0 and 3.5 gm total serum protein levels) It is also of interest that the Congo-red test is more often negative than positive in cases of primary amyloidosis and amyloidosis associated with multiple myeloma

DR WALTER F LEVER I did the electrophoretic analysis The albumin was 51 per cent, which is a value well within normal limits With the electrophoretic analysis normal albumin is 55 per cent

DR KRANES I think it is of interest that this man had a normal renal function until he had a sudden change

DR BAUER I overlooked this point I thought the nonprotein nitrogen was 150 mg per 100 cc before the hemorrhage

DR KRANES Before or after?

DR LEVER The nonprotein nitrogen rose first

DR KRANES I get the impression that the nonprotein nitrogen rose following the hemorrhage

DR BAUER Yes, on rereading the case history I find that is right I still think this patient had amyloidosis of the kidneys However, Dr Kranes is right about the sequence of events before and after the hemorrhage The hemorrhage was "the straw that broke the camel's back" and caused the renal ischemia that resulted in the rapid rise in the nonprotein nitrogen

CLINICAL DIAGNOSES

Plasma-cell myeloma

Uremia

Duodenal ulcer

DR BAUER'S DIAGNOSES

Multiple myeloma

Amyloidosis, associated with multiple myeloma

Tertiary syphilis

Syphilitic aortitis

Inactive central-nervous-system syphilis

Duodenal ulcer, healed

ANATOMICAL DIAGNOSES

Multiple myeloma, plasmocytic

Myeloma kidney

Retroperitoneal hematoma

Syphilitic aortitis

Benign ulcer of stomach

PATHOLOGICAL DISCUSSION

DR MALLORY Autopsy showed very characteristic multiple myeloma involving the marrow of all bones examined — the vertebra, ribs and sternum The plasma cells, as Dr Jacobson noted, were quite mature in type, although in the marrow tumors multinucleated cells are quite common It is rather unusual in cases of plasma-cell myeloma to see

many plasma cells in any of the viscera outside the bone None were found in this case Going back to the other features of the autopsy, there was an active peptic ulcer of the stomach, and there were two diverticula of the duodenum but no ulcers We did not find any evidence of amyloid disease The heart was normal except for a slight thickening of the aortic cusps The ascending aorta was diffusely dilated, and it was very difficult to decide whether this was arteriosclerotic or syphilitic I think it probably was burnt out and very inactive syphilitic aortitis The kidneys were a little large, weighing 410 gm, and showed the characteristic picture seen in Bence-Jones proteinuria The tubules were filled with casts and precipitated protein In a few cases foreign-body giant cells were noted around the casts, which is rather specific for the so-called myeloma kidney

We did not have permission to examine the central nervous system so that I cannot say whether or not there was evidence of syphilis there

DR BAUER No evidence of amyloid?

DR MALLORY No

DR BAUER And it was looked for?

DR MALLORY Yes — in significant amounts it could not be missed by any method

DR BAUER Some people disagree it may not be demonstrable in primary amyloid disease and in the type associated with multiple myeloma The Congo red may not be absorbed

DR MALLORY Yes, but one sees hyaline-like tissues whether or not it stains correctly with the method One can miss an isolated deposit of amyloid, for instance, one limited to the joints, in cases in which the extremities are not dissected, but generalized amyloidosis could not be missed if routine microscopical examination was done

DR BAUER So you would not miss it in the kidney?

DR MALLORY No

One other finding concerns the point that Dr Kranes made there was evidence of extensive hemorrhage within the body, — the retroperitoneal tissues, particularly around the pelvis, and the lymphoid tissues, were filled with old hemorrhage, much of which had coagulated, and was dark brown It must have been present many days before death So there was internal as well as external hemorrhage, which may have had something to do with the development of the renal insufficiency The purpuric tendency could have been due to renal insufficiency or to bone-marrow replacement in this case

diagnoses of tertiary syphilis and syphilitic heart disease with aortitis I well appreciate that in some cases of primary amyloidosis and the form associated with myeloma, endocardial and valvular amyloid deposits do occur

There are a number of questions one would like to answer. Were the joint symptoms a year before entry due to the multiple myeloma or the associated amyloidosis? In some cases of primary amyloidosis and the type associated with multiple myeloma large deposits of amyloid are found in the articular tissues. Such patients may have joint pain and swelling, and the amyloid deposits may be demonstrable on x-ray examination. Unfortunately, no x-ray films of the joints were taken, however, it seems fair to assume that they would have been normal and that there was no clear-cut evidence of skeletal involvement in this case. The other question to be answered is: Did this man have a duodenal ulcer as well as a gastric ulcer? (I did not realize this possibility until I saw the x-ray films.) We know that involvement of the gastrointestinal tract occurs in amyloidosis and that gastric ulcerations do take place. Should one explain the gastric lesions on the basis of the associated amyloid disease, or should one make a diagnosis of a benign gastric ulcer as suggested by Dr. Wyman? I must say that I prefer to "stick my neck out," and consider the gastric lesion as being part and parcel of the amyloidosis. Primary amyloidosis and the type associated with multiple myeloma may be characterized by diffuse vascular involvement. This was demonstrated in the case I was tripped on about a year ago¹ (I made the diagnosis of Osler's erythema group of skin diseases with visceral involvement.) Such cases may show marked deposition of amyloid in the media, sometimes with complete replacement thereof. In such cases one observes cutaneous manifestations, subcutaneous amyloid deposits and recurring purpura or purpura due to very slight trauma. In this case the bleeding occurred from all orifices. Of course, the patient may have bled from the gastric ulcer or the old duodenal ulcer, which Dr. Wyman thinks may have become activated.

As I said before, I think this patient had multiple myeloma with associated amyloid disease, amyloid deposition in the gastrointestinal tract, particularly the stomach, with associated ulcerations. As a rule the last are rather superficial. I doubt the presence of skeletal amyloidosis. The other diagnoses are syphilitic heart disease, syphilitic aortitis and a healed duodenal ulcer. I shall include also central-nervous-system syphilis because of the marginal spinal-fluid protein value and the abnormal colloidal gold curve—findings that indicate relatively quiescent or inactive central-nervous-system syphilis.

The apparently normal distribution of serum protein fractions (albumin of 5.06 gm and globulin of 2.05 per 100 cc) has been reported by others.²

The results obtained by the Howe technic and the electrophoretic method are not always comparable, as shown by Gutman et al.² The same investigators concluded that unless special precautions are taken, the Howe method (which gives high values for albumin in normal serum) occasionally gives much too high values for serum albumin in multiple myeloma, the error being due to the abnormal protein component in the 21.5 per cent sodium sulfate filtrate of some myelomatous serums.

DR ALFRED KRANES: Do you want to say anything about the kidneys?

DR BAUER: I meant to and forgot. I think the urinary abnormalities were due to amyloidosis. Marked albuminuria, hematuria (usually of a lesser degree than in this case) and pyuria have been noted in some cases of amyloidosis associated with multiple myeloma. Of course, there is always the possibility that the Bence-Jones protein precipitates out in the renal tubules. About a third of the cases of amyloidosis associated with multiple myeloma have renal involvement. Histologic examination of the kidneys shows amyloid in the glomeruli and in the media of vessels. I predict that the kidneys will show amyloid.

DR DANIEL S. ELLIS: Do you have to presuppose that amyloid deposits and not the myeloma itself caused this picture?

DR BAUER: No, but I think I am dealing with a disease akin to primary amyloidosis. I appreciate that in the case of a patient of seventy-five it is hazardous to explain so many findings on the basis of one disease. However, I prefer to do so, even though the chance of being wrong is great.

DR BERNARD M. JACOBSON: I would like to take issue with Dr. Bauer on a few items. I would not pass off the normal globulin so easily. I think it is a clinical finding against myeloma. On a statistical basis this is only the third case in this hospital with normal globulin by the Howe method.

DR BAUER: Have you read the article by Gutman et al.²

DR JACOBSON: No, I will. But I will not retract the statement. In the second place, these plasma cells as I saw them in the blood smear and bone marrow were extremely mature, quite different from the ordinary case of myeloma. One might wonder because some writers say that this maturity indicates a better prognosis than the immature cells. Obviously, that did not apply here. Hematuria and pyuria cannot be called common findings in amyloid disease.

DR BAUER: Nevertheless it is recorded in 2 cases. I reviewed.

DR JACOBSON: In this article?

DR BAUER: No, 2 cases reported by Eisen.¹

DR JACOBSON: That may be true, but it is not common in this hospital.

DR BAUER: Serum protein fractions in multiple myeloma are reported in some detail by Gutman.

ued prosperity is dependent on its readers and its advertisers, and may the twain frequently meet! Suggestions for bringing about, continuing and strengthening this happy union and for improvements in advertising readability will be welcomed. It goes without saying that efforts are constantly made to ensure advertising material only of the highest grade.

STREPTOMYCIN AS A PROPHYLACTIC AGENT

Soon after the discovery of streptomycin it was shown that this antibiotic is highly active against the gram-negative bacilli and against many of the other organisms that constitute the flora of the large bowel. It was also demonstrated that streptomycin given by mouth is poorly absorbed so that about 95 per cent of an orally administered dose could be recovered in the feces and only about 2 per cent in the urine.

Direct studies in experimental animals have shown that streptomycin is highly effective in reducing the total number of bacteria in the feces and that this reduction can be accomplished more rapidly and more thoroughly with streptomycin than with other available agents, particularly the sulfonamides. Some of the early studies in animals¹ and in man² gave no indication of the development of resistance by the fecal organisms. Subsequent investigations,^{3, 4} however, have indicated that there is a rapid replacement of the fecal organisms by streptomycin-resistant organisms. This tendency was less marked when the so-called enteric sulfonamide drugs, such as sulfasuxidine and sulfathaladine, were used in conjunction with streptomycin, but even the combination of such agents failed to prevent the appearance of the resistant strains.

The studies of Poth and his associates² have demonstrated the value of sulfasuxidine in the preoperative and postoperative care in surgical procedures on the bowel. In their animal experiments they also showed that open technics of anastomosis could more safely be utilized if adequate doses of sulfasuxidine were used. Streptomycin administered orally failed to maintain an alteration of the bacterial flora for a sufficient time to permit

the experimental evaluation of its effects on the healing of the bowel wound. When both sulfasuxidine and streptomycin were used, the results were essentially the same as when sulfasuxidine alone was used. The use of streptomycin alone had to be abandoned after the first few experiments because the immediate reduction in the bacterial count was not maintained.

Rowe and his co-workers⁴ have studied the fecal flora of patients before and after operations on the large bowel and attempted to determine the value of sulfathaladine and streptomycin as adjuncts to this type of surgery. They found that the fecal coliform organisms could be reduced 99.99 per cent in an average of three and a half days when the patient was given sulfathaladine in doses of 0.1 gm per kilogram of body weight per day in divided doses. With the oral administration of streptomycin in doses of 2 gm per day a similar reduction was accomplished in twenty-four hours. Reversion of bacterial counts due to resistant organisms was not observed with the sulfonamide but did occur with streptomycin, particularly when a dose of only 0.5 gm per day was used. The combination of the two drugs even in the larger doses did not entirely prevent this reversion. In the course of their studies Rowe and his associates observed a case in which a coliform organism became resistant to both drugs during the preoperative prophylactic treatment and was later responsible for a postoperative peritonitis. The infection proved fatal, since it obviously could not be affected by these chemotherapeutic agents.

On the basis of their preliminary observations these authors suggest that streptomycin should not be employed alone but that a preliminary test of sulfathaladine for five to seven days and streptomycin for about forty-eight hours or less is worthy of a trial. Actually, the data suggest that the combination used for no more than twenty-four hours is the best regime in preparation of the bowel for surgery. They emphasize the fact that prolonged administration of streptomycin is not desirable and that it is unlikely that the combination of the sulfonamides with streptomycin can alter the total bacterial counts for any prolonged periods.

More recently Lockwood and his co-workers,⁵ after noting the conflicting reports in the literature,

TEAMWORK

ANY undertaking prospers according to the quality of effort that goes into its various activities. The physician who practices his profession must be well grounded in its fundamental principles and skilled in their application. He must constantly add to his knowledge and, with the equipment thus assured, he must employ also his personality in gaining the confidence and the respect of his patients. He must be faithful, diligent, cheerful and self-sacrificing, and he must have also the co-operation of those with whom he labors.

The success of an industry depends primarily on the quality of its product. To ensure this quality, however, there must be comparable quality in the raw materials used and there must be skill and integrity in the workmanship. In order that the enter-

prise shall succeed there must be attractive but honest advertising, backed up by good salesmanship. The confidence of the consumer must be obtained and secured.

So it is with journalism, and even with medical journalism, for this professional activity must operate under the same economic laws that apply to the practice of a profession or the operation of a trade. If continuing success is to be enjoyed, the quality of the product must be maintained at a high level as the basic factor. This quality must also constantly be brought to the attention of new readers and possible subscribers, for with publications as with other living matter, a strong circulation is an essential of health.

Not only does the circulation itself bring to the journalistic tissues those corpuscular bodies known to the creditor class as hard cash, it implies also that element of readability with which all but the most pessimistic of advertisers are visibly impressed.

The lesson is obvious. Those who have products to sell will display their wares where they will be favorably noticed by the greatest number of prospective buyers.

Two complementary factors are necessary if the experiment in teamwork is to achieve its best results. The sellers must present their products, which must conform to the highest ethical standards, as attractively and as arrestingly as possible and the readers on their part must bear in mind that the advertising pages of a journal may prove just as valuable to them as its text, and that by reading the advertisements and mentioning the journal when they buy or make inquiries they are strengthening the confidence of the advertiser in the medium that he has selected.

The *New England Journal of Medicine* having just passed its one hundred and twenty-first birthday—its one hundred and thirty-seventh according to a more favorable way of reckoning—is doing very well in both particulars and is enjoying, in these critical years, its peak circulation as well as its highest advertising revenue to date. These increases, however, are barely sufficient to neutralize rising costs of publication and the *Journal* is not at all unmindful of the fact that its contin-

workers have alleviated thousands of desperate social situations by making modern treatment available. Its educational program has brought the word cancer out into the public eye and brought more and more early curable patients to the doctors' offices.

From the standpoint of the physician all this adds up to the fact that it is an organization whose every effort helps correct the kind of situation that leads unthinking people to clamor for Government medicine. If for no other reason than his interest in humanity as a whole, the thoughtful doctor will support this society by working for it or with it and by contributing to its drive. He will show the people that he appreciates what they are doing by giving generously himself and by asking his patients to give.

If any prospective contributor does not know his local treasurer or the address of his state headquarters, he may merely put his check in an envelope marked "Cancer, c/o Local Postmaster." This letter will go to his state headquarters.

DOCTOR NEEDED

ONE of the outstanding needs in the distribution of medical care is that of the rural district. This need is recognized in the pediatric survey recently conducted by the American Academy of Pediatrics, and in the creation of a committee on rural medical service by the American Medical Association in 1945. It is recognized in the controversial ten-year program of the federal security administrator.

Efforts are being directed toward the solution of this problem, not only by the agencies mentioned but by others, such as the Board of Missions of the Methodist Church that is currently trying to provide medical care for many rural areas. Outstanding among these medically needy communities, according to the Methodist Board of Missions and Church Extension, of 150 Fifth Avenue, New York, is Newton County, in northwest rural Arkansas. Here 10,000 persons are without a physician or a nurse and the nearest hospital is twenty-five miles from the county seat.

NOTES FROM THE MEDICAL EXAMINER

ASPHYXIATION FOLLOWING THERMAL BURNS OF THE FACE

Persons trapped in conflagrations may die as a result of damage to the respiratory tract without injury to the surface of the body.¹ The problem of whether smoke and irritant gases or tremendously heated air is the responsible agent has often been discussed.² In 1945 Moritz, Henriques and McLean³ reported an experimental study of the effects of inhaled heat, which showed that only when the original temperature of heated air is high enough to produce instantaneous burning of the skin and upper respiratory mucosa is there thermal damage to the pulmonary parenchyma. The amount of heat contained in the small volume of tidal air is the limiting factor for thermal injury of the air passages, whereas skin lying on the surface of the body is exposed to relatively enormous volumes of heated air passing across it by convection currents. For this reason it is safe to conclude that no damage to the respiratory tract *due to heat alone* can occur without burns of the face. Conversely, in the presence of burns of the face, there may be injury of the air passages.

Two of the 3 patients in the following case reports would probably have survived their burns had the attending physicians appreciated the hazard of respiratory obstruction coincident with burns of the face.

CASE 1 A 40-year-old man was removed from a conflagration in an abandoned dwelling at 5:30 a.m. In the building there were "500 cases of Sterno," the residue of numerous alcoholic sprees. Pressure dressings were applied to second-degree and third-degree burns of the face and hands, and to spotty areas of the shoulders and arms. The blood pressure was 120/70, and the pulse 100. Intravenous injections of glucose in saline solution were given. He drank milk frequently and talked easily, stating that he felt well. At 2:00 p.m. he was observed to be suddenly breathing with difficulty. Aspiration, artificial respiration and intracardiac adrenalin were ineffective, and death occurred at 2:15 p.m., 83½ hours after removal from the fire.

Post-mortem examination revealed the body of a well developed and well nourished man, 63½ inches in length, weighing 145 lb. The hair of the head was uniformly brown. There was second-degree and third-degree burning of the face, left shoulder and hand, right axilla, upper arm, forearm and hand. The total burned area was less than 10 per cent. Significant autopsy findings were fluidity of blood, edema and hyperemia of the lungs, the left weighing 360 gm. and the right 460 gm., extensive deposition of carbon particles throughout the trachea and bronchial tree, and laryngeal edema most marked at the glottis, reducing the laryngeal diameter of about 0.3 inch.

In this case the burns were of slight extent, the face severe. The carbonaceous material in the trachea and bronchi is proof that the products of combustion were inspired.

CASE 2 A 40-year-old man was removed from a conflagration in an abandoned dwelling at 5:30 a.m. In the building there were "500 cases of Sterno," the residue of numerous alcoholic sprees. Pressure dressings were applied to second-degree and third-degree burns of the face and hands, and to spotty areas of the shoulders and arms. The blood pressure was 120/70, and the pulse 100. Intravenous injections of glucose in saline solution were given. He drank milk frequently and talked easily, stating that he felt well. At 2:00 p.m. he was observed to be suddenly breathing with difficulty. Aspiration, artificial respiration and intracardiac adrenalin were ineffective, and death occurred at 2:15 p.m., 83½ hours after removal from the fire.

recorded their own appraisal of orally administered streptomycin as an intestinal antiseptic. They did careful serial quantitative bacterial counts in the feces of patients receiving streptomycin by mouth. Only half the patients showed a drop in the number of coliform organisms, and this drop was prolonged and significant in only a fourth of the cases. There was no significant reduction in the number of streptococci in 87.7 per cent of the cases, and 38.9 per cent failed to show any reduction in the clostridial counts in the feces. The bacilli demonstrated rapid development of resistance to streptomycin so that many became able to proliferate in the concentration of streptomycin present in the feces. The results in a small group of cases treated with streptomycin and sulfathaladine were also inconsistent. These workers concluded that streptomycin administered by mouth is unpredictable and unreliable, and its use in preoperative preparation of surgical cases is not recommended.

It is also noteworthy that streptomycin-resistant organisms may appear in the feces of patients who receive streptomycin only by intramuscular injection.⁶ This finding is not surprising since it has been shown that streptomycin-resistant organisms also appear in the throat cultures of 98 per cent of patients who have been under treatment with intramuscular injections of streptomycin for several days.⁷

In general, some of the properties of streptomycin—namely, its tendency to produce serious vestibular damage on prolonged use and particularly the rapid replacement of the bacterial flora by highly resistant strains—suggest that it is a very poor prophylactic agent in the usual sense. It may, however, be useful under certain circumstances provided it is given under optimal conditions. The data cited suggest that in cases of the usual gram-negative bacillary infections, such as might arise during large-bowel surgery or during manipulations of an infected urinary tract, streptomycin administered for not more than twenty-four hours prior to the operation may reduce the volume of infection at the operative site and thus diminish the chances of postoperative infection and thereby improve the healing process. If the bowel is to be opened a sulfonamide may be used for the same or a longer period preoperatively.

In cases of tuberculosis in which the organisms multiply more slowly and resistant strains may not appear in large numbers until after two or three weeks of streptomycin treatment, preliminary administration may be carried out for about a week before extensive operations on tuberculous lesions and still permit two weeks or more of treatment postoperatively with the expectation that the streptomycin effect will be sustained during this period. The longer the period of preoperative streptomycin treatment, the greater the risk of an increased number of resistant tubercle bacilli and the less the opportunity for the streptomycin effectively to cope with any postoperative spread of the tuberculous infection.

THE AMERICAN CANCER SOCIETY

DURING the last few years the American Cancer Society has raised and spent many millions of dollars on research, service and education. Positive accomplishments of its work may be found in all parts of the country. At the same time doctors, hospitals, federal, state and local government units, and individuals have accomplished much in this field. The local units of the Cancer Society in every city and town are now asking the people for more money. In view of the large efforts of the doctors, the Government and other organizations and individuals is this money needed?

The answer must be that it is. This organization is the best possible catalyst to stimulate and pull together the efforts of everybody. It is set up so that it is a true partnership of doctors and the people in this common effort.

Its research program has already affected the treatment of many kinds of cancer. Its devoted

CORRESPONDENCE

REPUDIATION OF AMERICAN MEDICAL ASSOCIATION ASSESSMENT

To the Editor I delayed paying the \$25 00 assessment of the American Medical Association until there was time for a statement of policy authorized by the Association. Now that this has appeared, I have decided not to pay the assessment of \$25 00 to support the policy of the American Medical Association because that statement as set forth in the February 19 issue of the *Journal of the American Medical Association* is too vague to be satisfactory, particularly as to legislation to provide the money to carry out its various items, and because the official answer of the American Medical Association to a group of protestants, who, to those familiar with American medicine, represent the cream of the profession, is unsatisfactory, since it does little more than call names and does not acknowledge the seriousness of the situation that called out this protest and does not indicate any intention of attempting to correct it.

This determination of mine not to pay the assessment is a protest against the present policy of the American Medical Association, not a support of governmental compulsory insurance to provide medical care along the lines proposed by President Truman, that I believe to be highly undesirable.

FURTHER COMMENT ON EXTRARENAL AZOTEMIA

To the Editor In the January 20 issue of the *Journal*, Appel and Townsend reported on an interesting case of "Extrarenal Azotemia" with recovery. No mention was made of the possibility of carbon tetrachloride poisoning. The possibility of carbon tetrachloride poisoning as a cause of uremia is frequently overlooked. The liver damage in this poisoning may be transient, and jaundice may be absent. It may be difficult to elicit a history of exposure to carbon tetrachloride because of the uncertain interval between exposure and renal shutdown. The differential diagnosis of any unexplained uremia should include the possibility of carbon tetrachloride nephrosis.

A CLINICAL SUGGESTION

To the Editor Skin-temperature determinations are frequently of considerable clinical value. The available methods vary from the application of the observer's hand to the use of electrothermometers such as the "dermatherm" and "dermalor."

With increasing interest in the study and treatment of diseases of the peripheral vascular and sympathetic nervous systems, I should like to suggest an instrument that is simple, inexpensive and adequately accurate for ordinary testing. It is an English skin thermometer. Its chief differences from the ordinary clinical thermometer are that the glass of the mercury-containing bulb is much thinner and that there is no trap, and therefore no shaking is necessary between readings.

It has been found precise to within 1°F when checked against the electric apparatus in the Hypertension Laboratory of the Massachusetts General Hospital (by Dr Davitt Felder). Attention was called to this thermometer by Dr Moses Suzman, of Johannesburg, in 1947. I have found none like it manufactured in this country. Anyone who is interested may procure these instruments in 4-inch or 8-inch sizes from L H Marks, Ltd, 1 Belfast Road, London, N 16.

FAMILY DOCTORS NEEDED

To the Editor Dr Henry F Howe's letter in the March 10 issue of the *Journal* should be sent to the dean and professors of medicine of every medical school in the United States. If the A M A would expend some of its so-called educational-fund assessment on the dissemination of this sort of plain common sense there would be far less chance of the public's demanding or even accepting socialized medicine.

At present the medical schools and large hospitals are engaged in turning out specialists with no regard for the necessity of general practitioners. Here in my own community, within twenty miles of Boston and access to all its facilities, with an increase of over 500 families in the last five years and the loss by death of two physicians, there has been no addition of qualified family physicians.

During this period I have had numerous young surgeons and other specialists inquire about the chance of establishing a lucrative practice. Not a single man has evinced the slightest interest in helping to carry the daily load of calls, which neither demand nor can afford a specialist. There is not even the excuse of lack of housing, since a most desirable house with adequate office arrangement is available.

The few general practitioners in Natick are exhausting themselves trying to provide medical coverage for the population. With long waits for both office and house calls it is no wonder that the public is becoming dissatisfied with the medical profession's handling of the situation. A serious epidemic would be a disaster.

I believe that many young medical students would gladly devote themselves to general practice, with its comparatively earlier financial returns, if the role of family physician were not looked down upon in the medical schools.

A medical profession that does not provide what the public needs or wants will have only itself to blame if the public turns to Government medicine to fill this lack.

NOTICES

BOSTON CITY HOSPITAL HOUSE OFFICERS ASSOCIATION

The following programs of the Boston City Hospital House Officers Association will be presented in the Evening Lecture Series

- April 11 The Surgical Problem of Carcinoma of the Female Genitalia Persistent or Recurrent after Conservative Treatment. Alexander Brunschwig, M D, attending surgeon, Memorial Hospital for Treatment of Cancer and Allied Diseases, and professor of clinical surgery, Cornell University Medical College
- April 12 Role of Iron Metabolism in Hypochromic Anemia. Carl V Moore, M D, associate professor of Medicine, Washington University School of Medicine, St. Louis
- April 14 Lower-Nephron Nephrosis. Baldwin Lucké, M D, professor of pathology, University of Pennsylvania School of Medicine.

These programs are held at 7:00 p.m. in the New Cbeever Amphitheater of the Dowling Building, Boston City Hospital. All interested persons are invited to attend.

HARVARD MEDICAL SOCIETY

A meeting of the Harvard Medical Society will be held in the Lower Out-Patient Department Amphitheater, Massachusetts General Hospital, on Tuesday, April 12, at 8 p.m.

PROGRAM

- Anatomy and Physiology of Splanchnic Pathways from the Viscera. Dr James C White
 - Anatomy and Physiology of Pain Pathways in the Brain Stem and Spinal Cord. Dr William H Sweet.
- A subsequent meeting will be held on May 10

sisted of demerol and penicillin at 3-hour intervals. He was said to show marked hemoconcentration and died at 7 39 p m — 19 hours after injury.

Post-mortem examination disclosed the body of a well developed and well nourished man, 71 inches in length, weighing 165 lb. The hair was extensively burned away. There was burning of the scalp, entire face, anterior portion of the neck, shoulders and both hands. The total area was 10 per cent of body surface. Severe edema of the face, scalp and neck was present. A pressure dressing had been applied to the head and shoulders with firm gauze binding crossing diagonally from head to axilla over the throat. The trachea and bronchi showed no gross injury. The right lung weighed 460 and the left 300 gm. Both lungs were crepitant throughout. Surrounding the lower pharynx and larynx there was massive edema. The glottis was almost occluded by submucosal edema.

This case demonstrates the additional obstructing force of edema extrinsic to the pharynx and larynx.

CASE 3 A 43-year-old Negro was removed from a conflagration resulting from a defective oil heater. He was admitted to the hospital at 7 30 a m, extensively burned but alert and oriented. Pressure dressings were applied. Shortly before death at 4 15 p m, alert attendants observed respiratory distress, and an emergency tracheotomy was performed but without benefit.

Post-mortem examination showed the body of a Negro 68 inches in length, with second-degree and third-degree burns of the right forehead and cheek, eyelids, lips, chin and anterior portion of the neck, with additional burns totaling about 70 per cent of the body surface. There was a tracheotomy tube passing down through a region of massive edema of the pretracheal tissues into the trachea. Surrounding the inner orifice of the tube was a pool of clotted and liquid blood obstructing both tube and trachea. Massive edema was present throughout the neck, and there was a moderate degree of glottic edema.

The interval of twenty-eight hours prior to autopsy reasonably explains the dissipation of edema fluid from the submucosal glottic tissues. The extraordinary degree of peritracheal and subcutaneous edema interfered with insertion of the tracheotomy tube and accounts for the hemorrhage from the incision funneling into the trachea.

In these cases, glottic edema precipitated asphyxiation. Whether an appreciable part of the edema was due to heat is debatable, but the burns of the face indicate close contact with the concentrated irritant gaseous products of combustion.⁴ Intubation and prophylactic tracheotomy are possible preventive measures, probably even superior to competent nursing care for thirty-six hours after injury.

*Five year median			

COMMENT

Diseases above the seven-year median were chancroid, chicken pox, diphtheria, dog bite, German measles, measles, mumps, scarlet fever and typhoid fever.

Diseases below the seven-year median were bacillary dysentery, poliomyelitis, salmonellosis and whooping cough.

Scarlet fever rises and falls in fairly predictable cycles over the years of reporting. The low year of such a cycle was 1947. In 1948 there was a reversal of the trend, and the disease can be expected to rise to another peak during the next year or two. The incidence of measles was the highest for February since 1935. That for chicken pox was the highest since reporting began in Massachusetts. The incidence of diphtheria remained high.

GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Anthrax was reported from Peabody, 1, total, 1.

Diphtheria was reported from Billerica, 2, Boston, 19, Chelsea, 1, East Brookfield, 3, Everett, 2, Malden, 1, Northampton, 1, Revere, 1, Taunton, 2, Wellesley, 1, total, 33.

Encephalitis, infectious, was reported from Lowell, 1, total, 1.

Infectious hepatitis was reported from Haverhill, 1, Williamstown, 1, Wrentham, 19, total, 21.

Meningitis, meningococcal, was reported from Fairhaven, 1, Greenfield, 1, Natick, 1, Westport, 1, total, 4.

Meningitis, Pfeiffer-bacillus, was reported from Haverhill, 1, Sharon, 1, West Boylston, 1, total, 3.

Meningitis, pneumococcal, was reported from Fitchburg, 1, Warren, 1, total, 2.

Meningitis, undetermined, was reported from Taunton, 1, Tyngsboro, 1, Worcester, 1, total, 3.

Salmonellosis was reported from Erving, 2, total, 2.

Septic sore throat was reported from Acton, 1, Arlington, 1, Boston, 6, Groton, 1, Medford, 1, Natick, 1, Orleans, 2, Randolph, 1, Westport, 1, total, 15.

Tetanus was reported from Brookline, 1, total, 1.

Trachoma was reported from Foxboro, 3, total, 3.

Trichinosis was reported from Williamstown, 1, total, 1.

Typhoid fever was reported from Tewksbury, 4, total, 4.

Undulant fever was reported from Lenox, 1, Saugus, 1, total, 2.

THE OCCURRENCE OF INFECTION AFTER PULMONARY RESECTION

A Study of the Effectiveness of Sulfonamides and Antibiotic Agents During a Six-Year Period (1942-1947)

CARROLL C MILLER, M.D.,* AND RICHARD H SWEET, M.D.†

BOSTON

AN ANALYSIS has been made of 427 cases of pneumonectomy and lobectomy during the years 1942 through 1947 at the Massachusetts General Hospital, and the results of the use of chemotherapeutic and antibiotic agents have been tabulated, with particular regard to complications caused by infection and to mortality. With few exceptions these complications occurred and were recognized during the postoperative hospitalization period, in several cases late recrudescence or fulmination of symptoms required readmission and further treatment. The latter cases have been included in the present study because the complications were considered to be the direct result of operation and its associated therapeutic program.

The years 1942 through 1947 were chosen because it was during this period that sulfonamides were first used, then penicillin and more recently streptomycin with increasing frequency. Sulfonamides were at first given in only a relatively small proportion of cases, and the manner in which they were administered in many cases would not be considered adequate in the light of the present concept of effective chemotherapeutic bacteriostasis. In 1944, when penicillin became available, the trend toward more complete prophylaxis and therapy was well under way, and by the end of 1946 all patients received penicillin. During the year 1946, a few selected patients received streptomycin in addition to penicillin, and in 1947 about half the patients received both drugs. It is the purpose of this study to show the definite decline in the rates of mortality and empyema during this six-year period as correlated with the use of chemotherapeutic and antibiotic agents.

In addition to the use of sulfonamides, penicillin and streptomycin during these six years, another

factor contributes strongly to the improvement in postoperative results. This is the diminishing use of the tourniquet in lung resections, and the adoption of the individual ligation technic in dealing with hilar structures. Such a technic was adopted before 1940,¹ and in the beginning of the series of cases reported here, the number of resections performed by the tourniquet method was already small. Later, in the past three years, the tourniquet and mass ligatures were never used as a method of controlling the hilus *en masse* proximal to the point of resection. In a very few cases it was necessary to employ the tourniquet temporarily to permit the removal of the lobe or lung, after this step the individual bronchovascular structures were isolated and separately secured. Judging from the high incidence of complications following the use of the tourniquet, and in recent years the infrequent occurrence of empyema with bronchopleural fistula or of massive fatal hemorrhage with the individual ligation technic, a distinct and significant, favorable influence may be attributed to the latter method. In recent years, another detail of technic used routinely at the hilus has been the careful suture of the bronchus with a single row of interrupted fine-silk sutures and complete capping of the closed stump with a pleural flap.²

Because of the diversity of diseases of the lung treated by resection and the number of different procedures performed, a mass grouping of all cases is of little significance except to give an over-all picture of results in a thoracic surgical service. On the other hand, a division of these cases into small sub-groups produces many series with no great importance from a long-range point of view. The value of individual group study, however, lies in the comparison afforded between the results of treatment in various diseases, and between different resection procedures (pneumonectomy, total lobectomy and segmental lobectomy in the various

MASSACHUSETTS PHYSICIANS CLUB

A meeting of the Massachusetts Physicians Club will be held at the Hotel Kenmore, Boston, on Tuesday, April 12, at 8 30 p m Dr John F Conlin, director of medical information and education, Massachusetts Medical Society, will speak on the topic "Socialized Medicine"

All interested physicians and medical students are invited to attend

MASSACHUSETTS CHAPTER, AMERICAN ACADEMY OF GENERAL PRACTICE

The first annual clinical meeting of the Massachusetts Chapter of the American Academy of General Practice will be held in Boston on Friday, April 15 The morning session will be held at the Peter Bent Brigham Hospital, and the afternoon and evening sessions at the Hotel Statler

PROGRAM

- 9 00-10 00 a m Ward Rounds Francis D Moore, M D, surgeon-in-chief, Peter Bent Brigham Hospital, and Moseley Professor of Surgery, Harvard Medical School
- 10 00 a m-12 00 m Clinic—Amphitheater—George W Thorn, M D, chief, Medical Division, Peter Bent Brigham Hospital, Hersey Professor of Medicine, Harvard Medical School, associate professor of medicine, Johns Hopkins University School of Medicine (Cases will be presented and discussed by all services)
- 12 00-12 30 p m Registration (Parlor A)
- 12 30-1 30 p m Luncheon (Hancock Room—tickets, \$3 00)
- 1 30-2 15 p m Emotional Factors in Psychosomatic Illness Bearing on Early Childhood Relationships Alfred Ludwig, M D, assistant psychiatrist, Massachusetts General Hospital
Five minutes' intermission
- 2 30-3 05 p m Premarital Counseling James C Janney, M D, assistant professor of gynecology, Boston University School of Medicine
Five minutes' intermission
- 3 10-3 55 p m Rh Factor William C Moloney, M D, assistant professor of medicine, Tufts College Medical School
Five minutes' intermission
- 4 00-4 45 p m Treatment of Hypertension William Dock, M D, professor of medicine, Long Island College of Medicine, and director of medicine, College Division, Kings County Hospital, New York
Five minutes' intermission
- 4 50-5 35 p m Virus Diseases from the Clinical Point of View Conrad Wesselhoef, M D, clinical professor of infectious diseases, Harvard Medical School
- 6 00-7 00 p m Business meeting
- 7 30-8 30 p m Banquet (tickets, \$4 50)
- 8 30 p m Our Social Structure as a Cause of Psychosomatic Disorders Paul Graves Myerson, M D, assistant professor of psychiatry, Tufts College Medical School, instructor in psychiatry, Harvard Medical School, and physician-in-charge of nervous and mental diseases, Boston Dispensary

All addresses are designed for everyday practical application to the needs of the general practitioner

Doctors' wives are cordially invited to the afternoon and evening sessions and to the banquet

Dress will be informal

NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

A meeting of the New England Society of Physical Medicine will be held in the Bigelow Amphitheater, Massachusetts General Hospital, on Wednesday, April 20, at 8 p m

The program, under the direction of Dr Arthur L Watkins, will be a Symposium on Rheumatoid Arthritis

ROSWELL PARK LECTURE AND MEDAL

Dr Evarts A Graham will deliver the Roswell Park Lecture of the Buffalo Surgical Society at the Kleinhans Music Hall, Buffalo, New York, on Thursday, May 5, at 9 p m The Roswell Park Medal for outstanding surgical achievement will be awarded to Dr Graham on this occasion

MASSACHUSETTS PHYSICIANS ART ASSOCIATION

The Massachusetts Physicians Art Association will hold its annual exhibit in conjunction with the annual meeting of the Massachusetts Medical Society at Worcester, May 24-26 Any member wishing to exhibit must send a list with the title, the medium, the evaluation and the approximate size of his pieces to Dr Charles E Ayers, 36 Pleasant Street, Worcester, Massachusetts, by April 25 Paintings must be framed for hanging Transportation and insurance will be arranged for without charge by the Massachusetts Physicians Art Association

ACADEMY OF NEUROLOGY

Establishment of the new American Academy of Neurology, latest of the specialty group organizations to come into existence, has been announced by its president, Dr A B Baker of Minneapolis

The purpose of the Academy is "to further and encourage the practice of clinical neurology and to stimulate teaching and research in neurology and allied sciences" The Academy has three grades of membership active membership open to all physicians who have been certified in neurology or neurology and psychiatry, junior membership open to those at present engaged in postgraduate study in neurology or awaiting certification, and associate membership for noncertified physicians whose interests are in allied fields

The first scientific meeting of the Academy will be held at French Lick Springs, June 1, 2 and 3, 1949

by several operators of varied experience, and this fact may also have influenced the statistical results.

Lobectomy for bronchiectasis presents the best immediate postoperative prognosis of all the diseases

This discrepancy seems to be due less to immediately resultant infection than to technical intrapulmonary or intrapleural factors such as infarction of a lobar segment by inadvertent interruption of a major

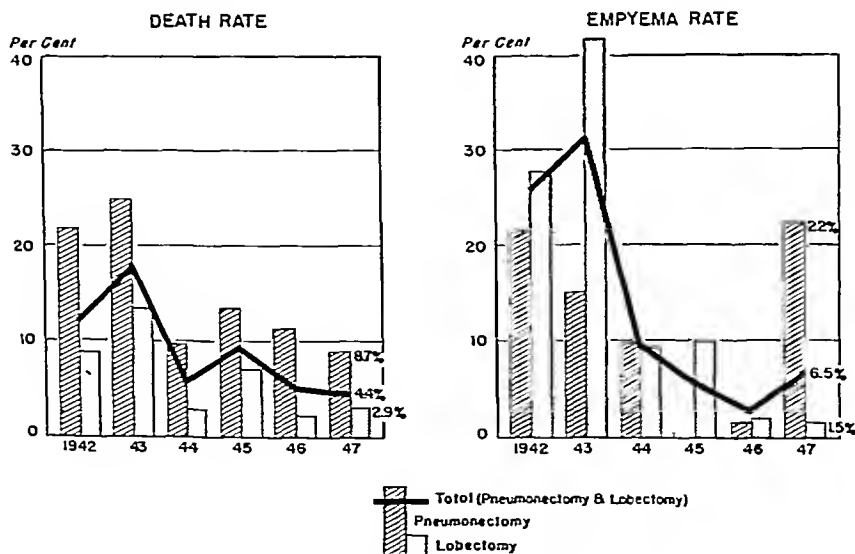

FIGURE 3 Mortality and Empyema Rates for Pneumonectomy and Lobectomy

in experienced hands (Fig 1). With the continued trial of segmental resection methods, there may be a variation in the complication-rate curve. It has

blood vessel to that segment, plugging of a bronchus with resulting atelectasis, inadequate aspiration of the bronchial tree during or after operation, com-

lobes) A suggested prognosis in each type of case is thereby offered

Four major disease groups are considered These are bronchiectasis, lung abscess, tuberculosis and carcinoma As indicated in Figure 1, lobectomy for bronchiectasis in the years 1943, 1944 and 1946 was associated with no mortality in 60 cases and with a total mortality for the six years of 3.9 per cent, in this group there were 4 cases of empyema in 1943, 1 in 1944, 3 in 1945, and none in 1946 or 1947 Lung abscess was associated with a relatively high incidence of complications, but improvement is seen in the last two years This incidence contributes mainly to the striking increase of empyema in all cases in 1943 In the most recent report on the treatment of lung abscess at the Massachusetts General Hospital, the importance of

and streptomycin In six years the gross mortality rate for all diseases treated by pneumonectomy and lobectomy dropped from 21.4 per cent and 8.3 per cent to 8.7 per cent and 2.9 per cent respectively, in 1947 none of the deaths were due to sepsis but instead to technical difficulties during operation (uncontrollable hemorrhage and plugging of contralateral bronchial tree with mucus or blood) and in 1 case to later cardiorespiratory failure manifested at autopsy by pulmonary congestion and edema In the first five years, through 1946, the empyema rate similarly dropped from 21.4 per cent and 27.7 per cent to 3.7 per cent and 2 per cent respectively In 1947 there were 5 empyemas in the group of 23 pneumonectomies (21.7 per cent) and 1 empyema among 68 lobectomies (1.5 per cent) Three of these, which were total empyemas subsequent to

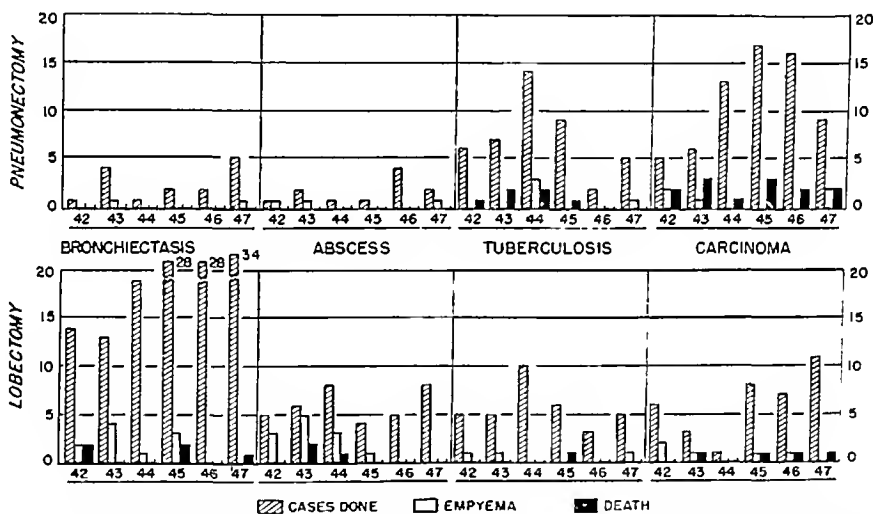

FIGURE 1 Incidence of Empyema and Death Following Pneumonectomy and Lobectomy, Arranged in Groups of Bronchiectasis, Abscess, Tuberculosis and Carcinoma and Further Subdivided into Yearly Blocks

lobectomy in selected cases was discussed as a more desirable method of treatment than drainage.³ As a result of the adoption of this policy, more lobectomies and pneumonectomies have been performed for this disease in the past few years. The tuberculosis data are essentially those reported in 1946, with the inclusion of the rest of the cases in that year and those in 1947, subsequent to that report.⁴ The cases of carcinoma bring into consideration other factors (resection for palliation, general condition of the patients and complicating infection) that may influence death and empyema rates, but they are not within the specific scope of this paper.

Figure 2 shows the improvement in empyema rates and death rates for lobectomies and pneumonectomies as separate groups coincident with the use at first of sulfonamides and later of penicillin

pneumonectomy, became evident several months after discharge following an apparently smooth convalescence. During these operations there had been no unusual, obvious contamination. Of the 5 empyemas complicating pneumonectomy, 2 were after operations for carcinoma, and 1 each after operations for abscess, bronchiectasis and tuberculosis.

Figure 3 demonstrates the same trends shown in Figure 2, but in simplified detail and in a different combination of data. During the six-year period the improvement in death rate after pneumonectomy, lobectomy and in the total number of resection cases grouped together is readily seen. A similar decrease in the empyema rate is obvious.

Figure 4 shows the total number of deaths during the six years as compared with the number of deaths associated with empyema. In 1944 it is seen that half the patients (2 out of 4) who died had

empyema, but thereafter there was a decline to 0. It should be stated at this point that during the period 1942-1947 the procedures were carried out

been our experience that patients who undergo a segmental resection do not have so smooth a convalescence as those who undergo total lobectomy^{5,6}

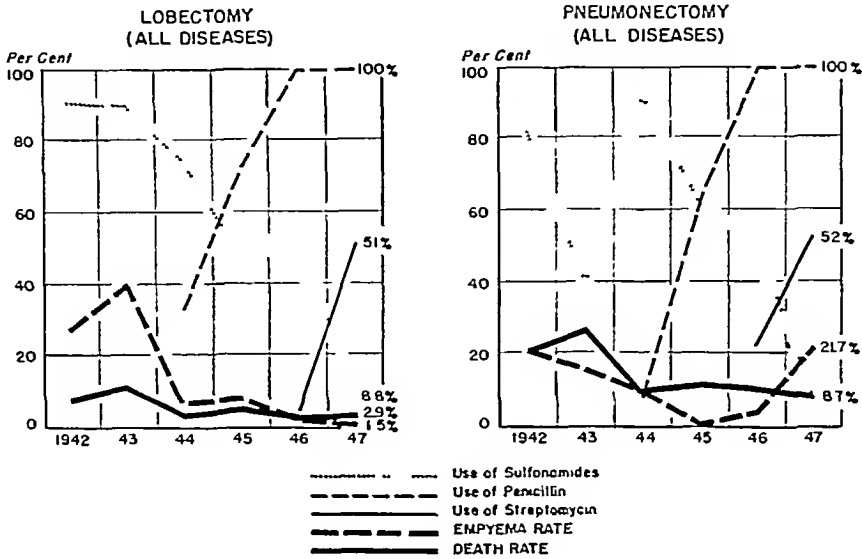

FIGURE 2 Incidence of Empyema and Death in Relation to the Use of Sulfonamides, Penicillin and Streptomycin

by several operators of varied experience, and this fact may also have influenced the statistical results.

Lobectomy for bronchiectasis presents the best immediate postoperative prognosis of all the diseases

This discrepancy seems to be due less to immediately resultant infection than to technical intrapulmonary or intrapleural factors such as infarction of a lobar segment by inadvertent interruption of a major

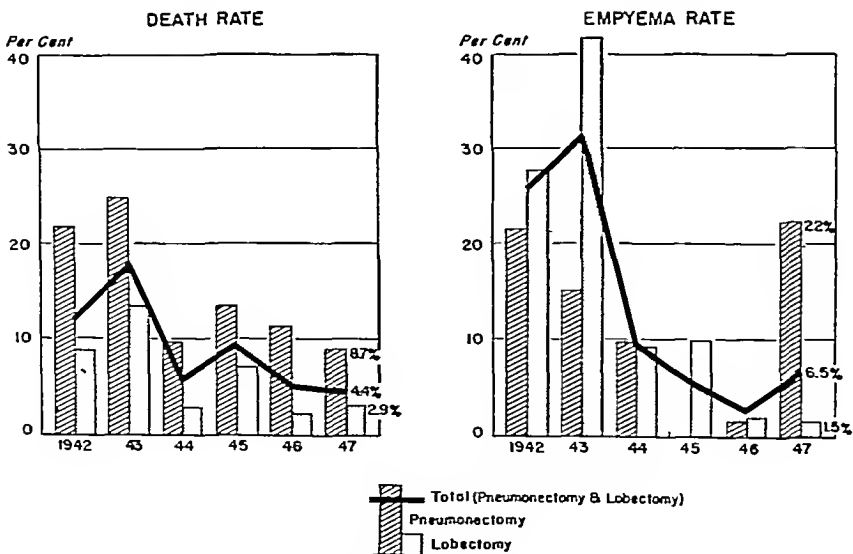

FIGURE 3 Mortality and Empyema Rates for Pneumonectomy and Lobectomy

in experienced hands (Fig. 1). With the continued trial of segmental resection methods, there may be a variation in the complication-rate curve. It has

blood vessel to that segment, plugging of a bronchus with resulting atelectasis, inadequate aspiration of the bronchial tree during or after operation, com-

pression atelectasis by accumulated pleural effusion, too extensive suturing of lobe surfaces in order to obtain pleuralization or hemorrhage into lung parenchyma beneath the suture line. Recently, according to the suggestion of other writers,^{5, 7, 8} several of the surgeons in this hospital have been either leaving the cut surface of the remaining segment of lung uncovered by pleura or using a circumferential marginal flap of pleura left purposely on the remaining segment during resection to be sutured over the raw parenchymal surface. The patients in whom this detail of technic has been used have appeared to recover more uneventfully than

chemotherapeutic and antibiotic agents is a valuable safeguard because although healing of the lesion may not occur without the benefit of surgery, the surrounding pneumonitis can be appreciably reduced as shown by roentgenograms, and spreading invasive infection, empyema and wound sepsis may be prevented in a large majority of cases.

In patients with wet bronchiectasis, the use of aerosol penicillin has reduced the amount of sputum and increased the patient's sense of well-being.⁹ This effect is somewhat more marked when penicillin is nebulized and inhaled than when it is given by intramuscular injection alone (Aerosol streptomycin was administered with aerosol penicillin to 15 patients in the whole series).

Mention should also be made of the use of penicillin and streptomycin injected into the pleural cavity after the demonstration of frank empyema. Two cases in this series were cured in this way without rib resection for drainage, one with penicillin and one with streptomycin, and 4 others were unsuccessfully treated. Such therapy must be early, massive (at least 100,000 units of penicillin or 1 gm of streptomycin, or both, daily) and persistent until the infection is controlled. As repeatedly emphasized in the recent and current literature, when a persistently recurring accumulation of pleural fluid following lobectomy or pneumonectomy is shown by culture, or by direct smear at the time of thoracentesis, to be contaminated by bacteria, penicillin or streptomycin, or both, depending on the nature of the infecting organisms, should be injected immediately and the therapy continued daily. The injection should be preceded by the aspiration of as much of the exudate as possible. It is important to institute this regimen early since, especially in cases of lobectomy, after three or four days the effusion may become loculated by the fibrinous process within it, and it is no longer possible to treat the empyema as a single cavity. During the diminution in amount of fluid as demonstrated by roentgenograms and the results of aspiration, and when the febrile reaction subsides, this medication can be administered less frequently and presently stopped.

The presence of a bronchopleural fistula that complicates an empyema suggests the interesting query, Is the fistula the cause or the result of the empyema, and how effective can specific bacteriostatic medication be in the presence of an open bronchial stump? An immediate, obvious answer is that if the bronchial suture line opens and remains open, contamination will occur and persist in spite of the use of antibiotic agents. This, it is believed, is not necessarily the case. If bacterial activity in the vicinity of a bronchial stump is adequately inhibited by the drug employed by virtue of both its systemic and its intrapleural concentrations, and if tissue healing proceeds at a normal

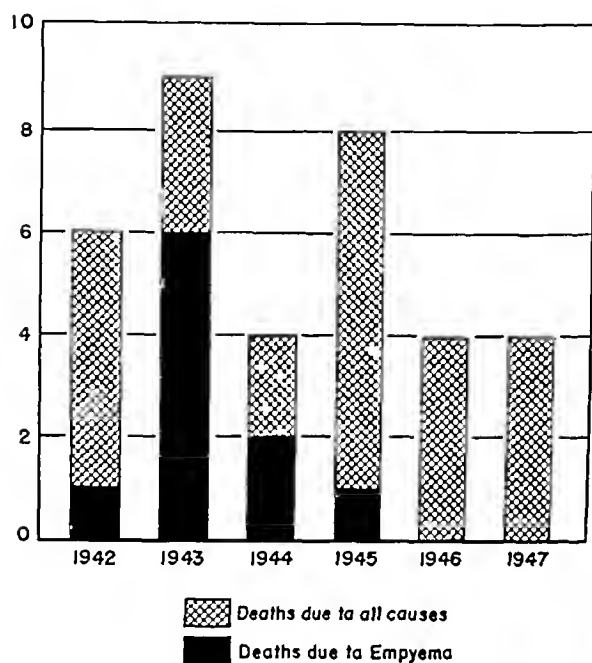

FIGURE 4 Total Number of Deaths for Each Year Compared with the Number of Deaths Complicated by Infection

many of those in whom the clamp-suture or non-stripping technic has been employed.

It should be emphasized that in the majority of cases of bronchiectasis, lung abscess or tuberculosis there is a mixed infection, involving organisms that may be resistant to currently available drugs. The development of more effective agents may be necessary to obtain better results. For example, streptomycin has been used together with penicillin, both in supposedly adequate large doses in a number of such cases. It was interesting to observe that often in these cases there was no demonstrable response to drug therapy as indicated by the temperature chart preoperatively. After operation, however, the course was extremely smooth, with no complications. This suggests that the most important factor of treatment is the extirpation of diseased tissue. On the other hand, protection with

rate, the bronchial fistula may well heal before the process becomes a chronic one. Thus, it is clearly indicated that satisfactory antibiotic protection must be combined with a careful technic and a thoroughly supportive nutrient regimen.

In this whole series, there were reported 11 bronchopleural fistulas, 1 in 1942, 7 in 1943, 2 in 1944, 1 in 1946, and 2 in 1947. The one patient in 1946 received penicillin before and after operation, and healed his fistula spontaneously within two weeks. The others in previous years received only sulfonamides, and in those who survived, healing was slow and prolonged. One of the 2 patients in 1947 who developed a fistula had had a pneumonectomy for tuberculosis and was given penicillin before and after operation, and streptomycin postoperatively only. The other, a patient who had a pneumonectomy for bronchiectasis, received penicillin intramuscularly and by the aerosol route preoperatively, in the chest at operation, and intramuscularly postoperatively — and streptomycin, only at operation, in the pleural cavity. The former was discharged to a sanatorium with the fistula still patent, and the latter required first a rib resection for drainage and later a thoracoplasty. Patients who developed fistulas in other years also had protracted convalescences.

The trend in fistula development closely follows that of empyema, and the problem of prevention should entail, in addition to the technic of closing the bronchus, the prophylactic and therapeutic principles used in the prevention or cure of infection in general.

A survey of pneumonectomy and lobectomy cases combined, with respect to sulfonamide, penicillin and streptomycin administration, reveals that in 1942, 6 patients received no drug therapy, and of these, 1 had empyema, in this group in which the drug was used there seems to be little or no correlation between the method of administration and the incidence of empyema. Twenty patients received a sulfonamide in the pleural cavity at operation and by parenteral administration postoperatively, and 5 had empyema. Twelve received it postoperatively* only, and 3 had empyema. Two received it preoperatively and postoperatively with no empyema. Seven received it in the pleural cavity at operation only, and there were 4 empyemas. One received it preoperatively and in the chest without resulting empyema. One received it preoperatively only and had empyema. One received it by all three methods and had empyema. Of the 3 fatal cases with infection in the form of empyema or parenchymal sepsis, none had what would now be called an adequate dosage of sulfonamide. Of course, these data are influenced strongly by the type of case (Fig 1), but a general conclusion from

the group as a whole indicates unsatisfactory protection with sulfonamides.

In 1943, a single case of empyema occurred among 15 patients who received no sulfonamide. Sixteen received the drug postoperatively, with 5 empyemas. Ten received it before and after operation, with 4 empyemas. In 4 it was used in the chest and postoperatively, with 3 empyemas. In 4 it was used preoperatively and postoperatively and in the chest, with 3 empyemas. Two received it preoperatively, with no empyema. Three of the 6 patients who died from sepsis had sulfonamide before and after operation, and of these, 1 received sulfanilamide in the pleural cavity at operation. The remaining 3 had it only postoperatively. The comment made in the above paragraph applies also to the year 1943, but the ineffectiveness of sulfonamides becomes more apparent.

In 1944 there were 2 cases of empyema among 56 patients who received sulfonamides alone, but on detailed analysis, the drug was given much more adequately than in previous years. Eleven had penicillin alone, with 2 empyemas, and 6 had both penicillin and sulfonamide, with 3 empyemas (the penicillin dosage and time of administration were inadequate). Sulfonamide was used in the chest at operation only once during this year and never thereafter. The 4 patients who died received a sulfonamide before and after operation, and 2 of these were given penicillin late in the postoperative period, but to no avail. Two of the 4 had definite empyema, in the remaining 2, pneumonia was suspected but not proved.

In 1945 sulfonamide alone was given to 23 patients, with 1 empyema, the drug, again, having been administered more thoroughly in most cases. Thirty-nine patients had penicillin alone, with 4 empyemas. Twenty-three had both, with no empyema. The 1 patient who apparently died of sepsis received sulfonamide preoperatively and postoperatively but no penicillin.

In 1946 penicillin alone was administered to 35 patients, and 1 developed empyema, which was cured by postoperative intrathoracic injection of penicillin. Forty-one received both penicillin and sulfadiazine, and there was 1 empyema. In this year 4 patients received streptomycin by aerosol administration preoperatively, and intramuscularly postoperatively, and an additional patient had it instilled in the chest at operation only. None of these had sepsis complicating recovery, and there were no deaths from sepsis.

During 1947, a year in which 6 cases were complicated by empyema, all patients (91) were given penicillin at some time during their hospital course, either before or after operation, or both. Some received aerosol penicillin before, and some after, operation. A large majority (69 patients) received an intrapleural injection at the conclusion of operation. Streptomycin was used with penicillin in

*Unless specifically mentioned as being administered intrapleurally or "in the chest," these drugs were given orally or intravenously (sulfonamides) or intramuscularly (penicillin and streptomycin).

pression atelectasis by accumulated pleural effusion, too extensive suturing of lobe surfaces in order to obtain pleuralization or hemorrhage into lung parenchyma beneath the suture line. Recently, according to the suggestion of other writers,^{6, 7, 8} several of the surgeons in this hospital have been either leaving the cut surface of the remaining segment of lung uncovered by pleura or using a circumferential marginal flap of pleura left purposely on the remaining segment during resection to be sutured over the raw parenchymal surface. The patients in whom this detail of technic has been used have appeared to recover more uneventfully than

chemotherapeutic and antibiotic agents is a valuable safeguard because although healing of the lesion may not occur without the benefit of surgery, the surrounding pneumonitis can be appreciably reduced as shown by roentgenograms, and spreading invasive infection, empyema and wound sepsis may be prevented in a large majority of cases.

In patients with wet bronchiectasis, the use of aerosol penicillin has reduced the amount of sputum and increased the patient's sense of well-being.⁹ This effect is somewhat more marked when penicillin is nebulized and inhaled than when it is given by intramuscular injection alone. (Aerosol streptomycin was administered with aerosol penicillin to 15 patients in the whole series.)

Mention should also be made of the use of penicillin and streptomycin injected into the pleural cavity after the demonstration of frank empyema. Two cases in this series were cured in this way without rib resection for drainage, one with penicillin and one with streptomycin, and 4 others were unsuccessfully treated. Such therapy must be early, massive (at least 100,000 units of penicillin or 1 gm of streptomycin, or both, daily) and persistent until the infection is controlled. As repeatedly emphasized in the recent and current literature, when a persistently recurring accumulation of pleural fluid following lobectomy or pneumonectomy is shown by culture, or by direct smear at the time of thoracentesis, to be contaminated by bacteria, penicillin or streptomycin, or both, depending on the nature of the infecting organisms, should be injected immediately and the therapy continued daily. The injection should be preceded by the aspiration of as much of the exudate as possible. It is important to institute this regimen early since, especially in cases of lobectomy, after three or four days the effusion may become loculated by the fibrinous process within it, and it is no longer possible to treat the empyema as a single cavity. During the diminution in amount of fluid as demonstrated by roentgenograms and the results of aspiration, and when the febrile reaction subsides, this medication can be administered less frequently and presently stopped.

The presence of a bronchopleural fistula that complicates an empyema suggests the interesting query, Is the fistula the cause or the result of the empyema, and how effective can specific bacteriostatic medication be in the presence of an open bronchial stump? An immediate, obvious answer is that if the bronchial suture line opens and remains open, contamination will occur and persist in spite of the use of antibiotic agents. This, it is believed, is not necessarily the case. If bacterial activity in the vicinity of a bronchial stump is adequately inhibited by the drug employed by virtue of both its systemic and its intrapleural concentrations, and if tissue healing proceeds at a normal

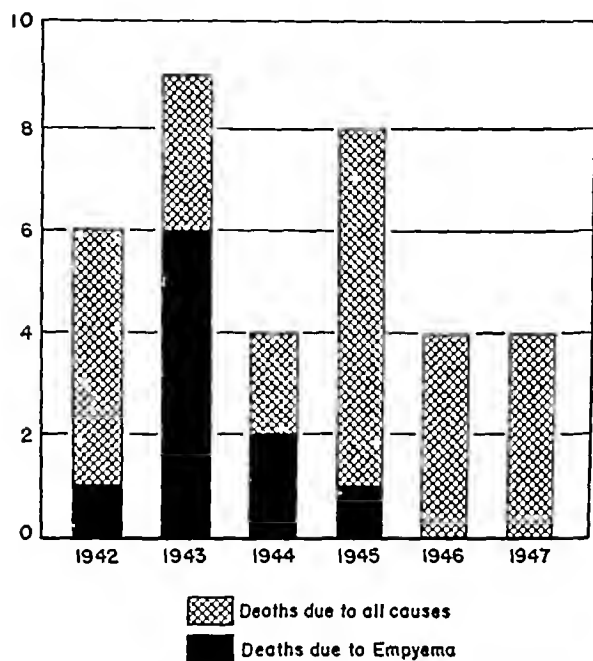

FIGURE 4. Total Number of Deaths for Each Year Compared with the Number of Deaths Complicated by Infection

many of those in whom the clamp-suture or non-stripping technic has been employed.

It should be emphasized that in the majority of cases of bronchiectasis, lung abscess or tuberculosis there is a mixed infection, involving organisms that may be resistant to currently available drugs. The development of more effective agents may be necessary to obtain better results. For example, streptomycin has been used together with penicillin, both in supposedly adequate large doses in a number of such cases. It was interesting to observe that often in these cases there was no demonstrable response to drug therapy as indicated by the temperature chart preoperatively. After operation, however, the course was extremely smooth, with no complications. This suggests that the most important factor of treatment is the extirpation of diseased tissue. On the other hand, protection with

amide alone — a fact that suggests that for optimum protection penicillin should be combined with a complementary agent

Figure 6 demonstrates the gradual shortening of the hospitalization period in each year with the gratifying conclusion that in addition to the all-important improvement in postoperative results, a monetary saving for the patient and an increased availability of beds for the hospital are achieved

The present routine chemotherapeutic program used for lung resection consists of the intramuscular injection of 300,000 units of penicillin (100,000 units every eight hours) and 1 gm of streptomycin (0.25 gm four times a day) daily for two days before operation. When there is fever or other signs and symptoms of toxicity, profuse sputum or evidence of pneumonitis by roentgenologic examination, penicillin may be administered for a week or ten days preoperatively. Aerosol penicillin, 50,000 units in 1 cc of physiologic saline solution, with or without streptomycin (0.25 gm) as indicated, is administered four times a day when expectoration is profuse preoperatively. In a few cases this form of chemotherapy has been used effectively in reducing the volume of sputum postoperatively. At operation, before the chest is closed, 100,000 units of penicillin and 1 gm of streptomycin dissolved in 30 cc of physiologic saline solution are instilled into the pleural cavity. Intramuscular injection of both drugs (100,000 units of penicillin and 0.25 gm of streptomycin every six hours) is continued for five or six days, or until the patient's temperature chart has been normal for three days. The use of penicillin and streptomycin intrathoracically in the event of suspected empyema after operation has been described above. When infection is present either before or after operation, the dosage and frequency of administration are increased.

Since the conclusion of the period covered in this study, streptomycin has been administered in addition to penicillin in *all* cases of lung resection as a routine adjunct in therapy with the hope that the figures herewith presented will be improved in immediately succeeding years.

SUMMARY AND CONCLUSIONS

Four hundred and twenty-seven cases of lung resection at the Massachusetts General Hospital in a six-year period (1942-1947) are reviewed with the specific intent of demonstrating the trend of infection and mortality rates in reference to the use of chemotherapeutic and antibiotic medication. The incidence of empyema and septic deaths is especially stressed. Intrapulmonary infection postoperatively is not considered in detail because of the difficulty in determining the exact extent and nature of the lesion in cases that do not come to subsequent operation or autopsy. Wound sepsis has been practically nonexistent in this series of

operations. Silk-suture material has been used almost invariably in the chest-wall closure.

The broad groups of lobectomy and pneumonectomy, as well as the four major disease entities in pulmonary pathology, — bronchiectasis, abscess, tuberculosis and carcinoma, — have been analyzed with respect to the obvious improvement in operative results. The data show a significant decline in infection and mortality rates, in the ratio of nonseptic to septic deaths and in the duration

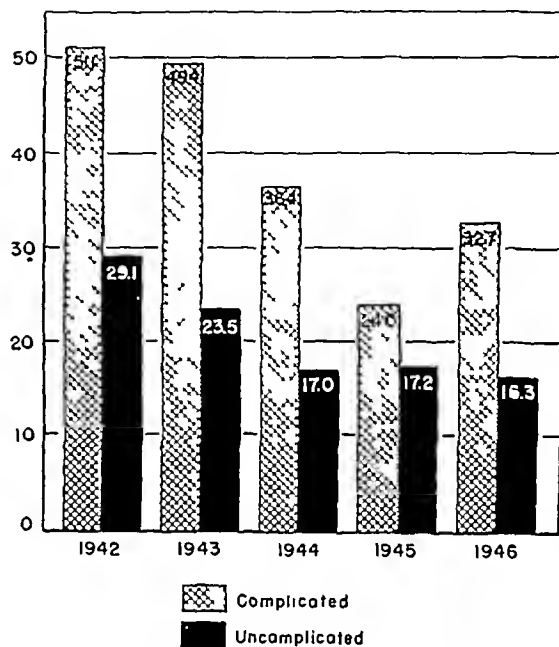

FIGURE 6 *Average Number of Days Spent in the Hospital after Lung Resection in Both Complicated and Uncomplicated Cases*

of hospital confinement for patients with uncomplicated and complicated postoperative courses.

Finally, a brief outline is given of the current regimen of protective medication used.

Chemotherapeutic and antibiotic agents seem to have a valuable place in the program of surgical treatment of pulmonary disease.

Drug therapy must be adequate and complete — that is, it must be given preoperatively and postoperatively. The use of penicillin and streptomycin in the pleural cavity at the conclusion of a resection cannot be easily evaluated, but it is assumed that it contributes to better results.

All cases must be carefully studied from a bacteriologic standpoint, and the proper agent and dose selected for the individual patient.

Early postoperative bronchoscopic aspiration should be used when there is failure of expansion as a result of bronchial obstruction, and prompt thoracentesis should be done in the presence of appreciable effusion. Intrathoracic instillation of

the same manner of administration in 46 cases Sulfonamides were given (without streptomycin) in 5 cases in the early part of the year before streptomycin became freely available, and in 3 additional cases with streptomycin as well. One of the latter patients received a sulfonamide postoperatively specifically for a bladder infection, and the other 2 had it preoperatively with streptomycin used only in the pleural cavity at operation.

A detailed analysis of the drug therapy given in the cases of empyema in 1947 indicates an inadequacy of streptomycin administration in the light of our present concept, for only 1 patient received streptomycin preoperatively and only 2 received it intrapleurally. (Four of the tuberculous patients

some of these organisms to the medication given. In the cases of tuberculosis we have been particularly mindful of this problem when streptomycin has been given for a period of several weeks before proposed operation and when its use after operation has been planned. Sensitivity studies have usually been done in the sanatorium before the patient comes to us, and care has been taken to avoid prolonged administration with its danger of both desensitization of the organism and toxicity to the patient. In the nontuberculous patients, also, it is indeed probable that certain cases that responded poorly to antibiotics did so because of natural or acquired resistance of the infecting organisms. However, the over-all improvement seen

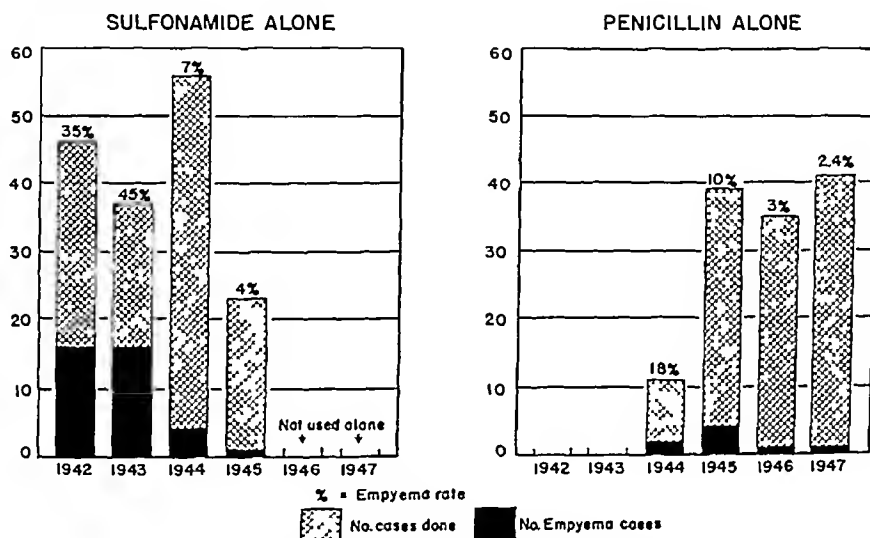

FIGURE 5 Incidence of Empyema in Each Year, First with Sulfonamide Administration Alone, and Then with Penicillin Alone

were not given intrapleural streptomycin, but of these only 1 developed empyema.) Three of the 6 patients with empyema received penicillin adequately (according to present standards), but 2 received it only postoperatively. Five of these cases were pneumonectomies—for carcinoma (2), abscess (1), bronchiectasis (1) and tuberculosis (1). The 1 lobectomy was done for pneumatocele. In none of the cases was there any error in technic or untoward factors that had not been encountered many times previously. Thus, there seems to be at hand no satisfactory explanation for the disappointing rise (Fig. 3) in the empyema rate for pneumonectomy in this year as contrasted with that of the preceding three years.

Except in rare cases in the total group of cases reported here, studies of the sensitivity of infecting organisms to antibiotic substances were not done, and the agents used were administered empirically without specific regard for possible resistance of

in this six-year period suggests that in general the sensitivity problem per se does not definitively affect the trend of results. In most cases the infecting organisms appear to be susceptible, or the antibiotic agent is not administered for a sufficiently long time to alter the sensitivity of the organism. On the other hand, more detailed attention to these factors should enhance the improvement already effected, and give a more accurate picture of the role that these agents play in certain refractory cases of postoperative infection.

The relative decline of empyema rate associated with the use of each of the two earliest chemotherapeutic agents alone (sulfonamide and penicillin) is indicated in Figure 5, in an attempt to evaluate the trend in the respective series. There is a more consistent drop to a lower level with penicillin than with sulfonamides. However, it will be noted that in 1944 and 1945, there was a higher incidence of empyema with penicillin alone than with sulfon-

bulk of the fibrinogen of normal human plasma and a globulin active in reducing the clotting time in hemophilia¹⁰). The fibrinogen content of the total plasma was roughly estimated for the patient, and 4.80 gm of Fraction I (24 vials) dissolved in distilled water was given rapidly intravenously by syringe. The clotting time at 2:30 p.m. was 5 minutes, and the bleeding time was 5 minutes. The patient's general condition had deteriorated; she was stuporous and vomited brownish fluid. Another 1000 cc. of blood was started, and a sterile vaginal examination was attempted but the patient began to flow profusely from below. She was quickly prepared, and at 4:00 p.m. a rapid cesarean section was performed. The uterus was plum colored and infiltrated with blood, and it was removed by a rapid hysterectomy. The surgeons and observers agreed that after the removal of the uterus bleeding seemed to cease, subsequently no further bleeding from the gums or into the skin was noted.

After the operation the patient developed a moderate degree of shock, the blood pressure was 60/40, and the pulse 160. After a transfusion of 1000 cc of whole blood she rallied, at 7:00 p.m. the clotting time was less than 1 minute and the bleeding time was normal. At 8:00 a.m. on February 2, the patient voided and her general condition was fairly good. The clotting time was 1 minute, no abnormal bleeding was noted but because of a low hematocrit (22 per cent) a transfusion of 1000 cc. of blood was given.

The subsequent course was uneventful, the bleeding and clotting times were within normal limits, and although the patient was literally "black and blue" from head to foot, she dangled her legs on February 3, was out of bed on February 5 and was discharged on February 12. She was rechecked periodically for several months after this episode, and all blood studies were within normal limits.

Autopsy on the infant revealed a macerated fetus with no special findings. The uterus and placenta were studied by Dr. Arthur Hertig, who reported the following pathological findings:

Examination shows a slightly premature placenta. Probable intrauterine death is evidenced by fibrosis of villi. There is premature separation of the toxic type and moth-eaten degeneration of trophoblasts. Hemorrhage into decidua is noted. The uterus is of the couvulaire type.

Owing to marked post-mortem changes, the amount of syncytial degeneration is impossible to evaluate. There is no atheromatosis of decidual sinusoids.

Unfortunately the uterus, after its removal, was placed in formalin solution for about 10 minutes. Subsequently studies on extracts of the organ (by Dr. O. W. Smith) failed to reveal any evidence of fibrinolytic activity, but it was believed that the formalin may have destroyed the labile fibrinolysin.

The most important blood specimens were those obtained at 6:00 a.m. and 8:00 a.m. on February 1, before the administration of blood and fibrinogen. Since only small amounts of these oxalated and clotted blood specimens were available, experiments were limited. The immediate problem was to determine the cause of incoagulability of the blood and this was investigated, insofar as possible, by a study of each of the various clotting factors.

There was no evidence in either clinical or laboratory studies of liver damage in this patient. Although rare, hypoprothrombinemia has been reported in the absence of obstructive jaundice and liver disease, in this case the prolonged prothrombin clotting time suggested the possible diagnosis of hypoprothrombinemia. However, the fibrin clot formed during the test was so scanty that the lack of fibrinogen was suspected. The addition of thrombin to the blood and plasma specimens obtained at 8:00 a.m. failed to produce coagulation and this finding, in the light of subsequent observations, proved that the lack of fibrinogen was the cause of the clotting defect.

Addition of calcium to blood and plasma of this patient did not restore coagulability; consequently lack of calcium was readily ruled out.

No evidence of an anticoagulant was found in the patient's blood. Direct addition of pretransfusion whole blood and plasma to normal blood and plasma caused no inhibition of clotting.

Addition of potent bovine thrombin to pretransfusion specimens of the patient's whole blood and plasma did not cause coagulation. Subsequently fibrinogen determinations

carried out on oxalated pretransfusion specimens revealed a complete absence of fibrinogen. Specimens obtained during the evening following operation showed a fibrinogen level of 0.5 gm per 100 cc., and specimens obtained three days postoperatively gave a fibrinogen value of 0.35 gm per 100 cc. It seems unquestionable that the incoagulability of the patient's blood was due to a complete lack of fibrinogen.

Afibrinogenemia is a rare disease that has been reported as a congenital defect and in severe liver disorders^{11, 12}. Neither of these causes could be established in this case. In view of the recent work of the Smiths^{14, 15} and the studies of other investigators on fibrinolysin, the explanation for the lack of fibrinogen and of fibrin in this patient seemed to rest most logically on the presence of a fibrinogenolysin or a fibrinolysin.

Observations on the small clot formed in the blood specimen obtained at 6 a.m. after standing overnight showed that the clot, although small, had not lysed. For several days after delivery, experiments were carried out on the pretransfusion serum specimens to demonstrate the presence of a fibrinolysin, but no lysis of clots formed from fibrinogen (Fraction I) and normal plasma was observed. However, experiments on the pretransfusion plasma (kept in a deep freeze) indicated that when fibrinogen (Fraction I) was added to this plasma and allowed to stand at 37°C overnight, no clotting occurred on the addition of thrombin to the mixture. On the other hand, when normal human plasma was used as the source of fibrinogen a clot occurred when thrombin was added. This observation seemed to indicate that there was a protective antifibrinogenolysin in the normal plasma and suggested that the lack or destruction of *antifibrinogenolysin* was the cause of the afibrinogenemia in this patient.

DISCUSSION

It seems well established that the cause of the *coagulation defect* was the complete lack of fibrinogen. The occurrence of acquired afibrinogenemia is extremely rare, especially in the absence of liver disease. Dieckmann,² in 1936, reported that in 5 of 11 cases of abruptio placentae extremely low fibrinogen levels were found, after delivery fibrinogen returned to normal. In one case Dieckmann² states that "the blood failed to clot in the test tube" and this patient "bled from the gums, stomach, uterus and into subcutaneous tissues." No detailed studies on the clotting mechanism were carried out in Dieckmann's cases, and he attributed the clotting defect to a lowering of the fibrinogen content due to blood loss and the mobilization of fibrin at the site of placental separation.

In 1946 Tagnon and his associates¹⁶ described, in a paper on fibrinolysis, a patient with incoagulable blood after a post-partum hemorrhage. Fibrinogen added to the patient's plasma, which had been collected shortly before death, clotted, but the clot dissolved within an hour. This group of investigators postulate that shock, especially that associated with hemorrhage and burns, results in anoxia with a release of a tissue factor that may have a precipitating effect on the production of fibrinolysin. However, in the case reported above, the patient was not in shock when her blood was first found to be incoagulable, moreover, fibrinolytic activity in the blood has been described in a variety of conditions unassociated with shock.

It must be admitted that the present knowledge of fibrinogenolysis and fibrinolysis is in a confused and uncertain state. MacFarlane¹⁷ states that

massive doses of penicillin and streptomycin may be effective in preventing or curing empyema

Aerosol penicillin with or without streptomycin is of benefit when sputum is profuse

It is believed that these agents also minimize the tendency to the development of pneumonitis in atelectatic areas of lung tissue, which frequently occurs postoperatively

ACQUIRED AFIBRINOGENEMIA IN PREGNANCY*

WILLIAM C. MOLONEY, M.D.,† WILLIAM J. EGAN, M.D.,‡ AND ARTHUR J. GORMAN, M.D.§

BOSTON

ONE of the most catastrophic events in obstetric practice is the occurrence of a fulminating hemorrhagic diathesis usually associated with toxemia of pregnancy and toxic separation of the placenta. Although uncommon, this usually fatal disorder has been encountered by most obstetricians of long experience.¹⁻³ For many years it has been suspected that there was a common etiologic background for this hemorrhagic disorder and toxemia of pregnancy, and it has been postulated that the uterus and its contents were the source of a toxic factor.²⁻⁶ In spite of the various theories advanced no toxic substance has actually been identified in the blood of patients with toxemia of pregnancy.

Although the occurrence of incoagulable blood, in what has been called the "calamitous" toxic patient, has been described by a number of authors,^{2, 3} the characteristics of the defective clotting mechanism have not been clearly established. Recently, a patient was encountered with this hemorrhagic disorder in pregnancy, and the following report is an account of the case with certain observations on the nature of the incoagulability of the blood.

CASE REPORT

Mrs. T. W., a 25-year-old gravida II, whose estimated date of confinement was January 30, 1948, entered the hospital because of lower abdominal pain and bleeding from the gums. She had been well throughout her pregnancy except for a prior admission to the hospital at about the 8th month for lower abdominal pain. At that time after 48 hours she was discharged with a diagnosis of false labor, the blood pressure and urinary findings were within normal limits. Throughout the last month of pregnancy she had lower abdominal discomfort and some dull pain, but at no time was there elevation of the blood pressure or abnormal urinary findings.

On the evening of January 31 the lower abdominal pain became more severe, and about 10:00 p.m. the patient noted spontaneous bleeding from the gums. Both the pain and

bleeding from the gums became worse, and she was admitted to the hospital at 1:00 a.m. on February 1.

The past and family histories were free of any evidence of abnormal bleeding tendency. In general her health had been excellent except that at the age of 15 the gall bladder and appendix had been removed. The patient had had one prior pregnancy, 2 years before, she had given birth uneventfully to a full-term, normal child. There was no history of toxemia during the first pregnancy, but she had noticed slight bleeding from the gums.

The patient complained of severe lower abdominal pain, and the uterus was tense and painful to palpation. The fetal heart was not heard. An unusual feature was the obvious bleeding from the gums, there was no ulceration, but the gingival margins were slightly swollen and free bleeding occurred from these areas. At 4:00 a.m., after an obstetric consultation, the clotting time was found to be greatly prolonged. Two hours later the patient was in good general condition, but the bleeding from the gums was more profuse and it was noted that wherever injections or venipuncture had been performed, ecchymotic areas appeared. Moreover, the uterus seemed larger and more painful. At this time, more detailed blood studies were carried out. The clotting time was rechecked at 37°C by a modified Lee and White⁷ technic, and the blood clotted as a poor gel only after 16 hours. The capillary fragility test was strongly positive, and the bleeding time (Duke⁸ method) was 14 minutes. Later, this puncture wound bled spontaneously for several hours. Blood smears showed numerous platelets present. The prothrombin clotting time (Quick⁹ procedure) was prolonged to 42 seconds, with a 14-second control, and it was noted that the fibrin clot was a poor film. Because of the prolonged prothrombin clotting time, 60 mg. of vitamin K was given intravenously at 8:00 a.m. At 8:30 a clotting time showed the blood to be incoagulable, after standing for 24 hours no clot formed. A transfusion of 1000 cc. of whole blood was given, and at 11:00 a.m., the determination of the clotting time was repeated. A poor gel formed in 15 minutes, but it was not a good blood clot and another 1000 cc. of blood was administered. The patient at this time was bleeding freely from the gums, and the bleeding-time puncture wounds were also bleeding spontaneously. Vaginal staining began, and the patient lapsed into a semicomatose state. Meanwhile further studies on the blood specimens taken at 6:00 and 8:00 a.m. revealed that the addition of thrombin did not cause the blood to clot. It became apparent that there was complete absence of fibrinogen in the patient's blood, and a supply of Fraction I (Cohn)¹⁰ was obtained. (Fraction I contains the

*The Fraction I of normal human blood plasma used in this case was processed by the American National Red Cross from blood that it collected from voluntary donors. NITRATE METHEMOGLOBINEMIA

HAROLD MARCUS, M.D.,* AND JOY R. JOFFE, M.D.†

BROOKLYN AND NEW YORK CITY

MORE than forty years have passed since the first report of a fatal case of methemoglobinemia secondary to bismuth subnitrate ingestion.¹ Fifteen years ago Roe² reviewed the subject and re-emphasized the hazards attending its use. Nevertheless, during the past four years 3 more cases have been reported.³⁻⁵ A recent experience with a newborn infant has prompted us to review the general subject of nitrate methemoglobinemia, with emphasis on the causes, the types encountered, the mechanism involved and the rationale of present-day therapy.

Thirty cases of methemoglobinemia secondary to bismuth subnitrate, ammonium nitrate and nitrates in well water have been reported. The case reported below followed the ingestion of bismuth subnitrate on prescription.

We wish to point out that 4 of the 5 fatal cases of nitrate methemoglobinemia were in the group that followed bismuth subnitrate administration. Hence it is our opinion that still another warning to the medical profession regarding its use is indicated particularly in view of the rapidly favorable outcome following the application of accepted therapeutic procedures.

CLASSIFICATION OF METHEMOGLOBINEMIAS

Methemoglobinemia may occur during the course of various diseases or may follow the ingestion of a variety of toxic agents. A slight modification of Ferrant's⁶ classification is as follows:

Plasma methemoglobinemia In this variety the methemoglobin is formed in the plasma after the liberation of hemoglobin from the red blood cells by hemolysis. This may occur in blackwater fever, eclampsia, paroxysmal hemoglobinuria, anaerobic sepsis and Winckel's disease of the newborn.

Cellular methemoglobinemia In this variety hemoglobin, which contains iron in its ferrous form, is oxidized within the red blood cell by various agents to methemoglobin, which contains iron in its ferric form. This type is further subdivided into idiopathic or enterogenous — according to van den Bergh,⁷ nitrite is formed in the bowel from nitrate by nitrite-forming organisms and absorption is encouraged by a damaged intestinal mucosa — and toxic, which comprises the largest

and most important group of methemoglobinemias (the agents responsible include primarily the drugs containing nitro and amino groups, such as derivatives of aniline, certain sulfonamides, nitrates and nitrites⁸⁻¹⁰).

Our interest centers on the methemoglobinemias produced by nitrate ingestion.

REVIEW OF THE LITERATURE

According to Beck,¹¹ cases of bismuth subnitrate poisoning were reported as early as 1793, but impurities such as arsenic were thought to be responsible. Eusterman and Keith¹² cite Gamgee¹³ as the first to demonstrate in 1886 that amyl nitrite could produce methemoglobinemia. In 1906 Bennecke and Hoffmann¹ reported the first fatal case of methemoglobinemia following bismuth subnitrate ingestion. Shortly afterward, Böhm¹⁴ presented a report of a fatal case of methemoglobinemia following the administration of bismuth subnitrate by enema. He believed that intestinal putrefaction accelerated nitrite formation and rapid poisoning and stated that in fatal cases patients invariably suffered from intestinal disease. Thus, the danger of administration of bismuth subnitrate to infants, particularly when intestinal dysfunction existed, was established over forty years ago. Nowak and Gütig¹⁵ showed that adults were not immune to nitrite poisoning after bismuth subnitrate. In reviewing the literature, Beck,¹¹ in 1909, made the first concise contribution on the general subject of poisoning due to nitrate, though limiting himself to bismuth subnitrate.

Years later, Eusterman and Keith¹² reported 2 nonfatal cases of methemoglobinemia in adults following the administration of ammonium nitrate as a diuretic. In both cases there was evidence of intestinal dysfunction. Tarr¹⁶ collected 9 cases of methemoglobinemia following the ingestion of ammonium nitrate, of which he personally observed 4. In his cases renal impairment rather than intestinal dysfunction was the common denominator.

Roe,² in 1933, reported the fourth case of methemoglobinemia due to bismuth subnitrate ingestion and recommended the use of bismuth subcarbonate in its place for the treatment of diarrhea.

In the past few years a series of papers on methemoglobinemia due to the ingestion of well water of high nitrate content have appeared. Schwartz and Rector¹⁷ reported a case of idiopathic methemoglobinemia in an infant fed a powdered milk formula and living in the country. Comley,¹⁸ in describing 2 cases of this type, clarified the above

"plasminogen of normal blood is of a potential activity to destroy the total fibrinogen of normal blood in a few minutes" Plasmin is held in an inert form by an antifibrinolytic, antiplasmin. Plasmin can be activated by a variety of conditions, which either destroy antiplasmin or activate plasminogen. MacFarlane¹⁷ indicates that the mechanism of plasmin activation is obscure, and he states that it may be concerned with shock, tissue breakdown, blood coagulation and other phenomena.

Smith⁵ recently discovered in menstrual fluid a euglobulin that is both a vascular toxin and a fibrinolysin. Moreover, he extracted from the serum of toxemic and other patients a euglobulin with fibrinolytic activity similar to that found in menstrual discharge. In the hypothesis advanced, the source of the fibrinolytic factor is in the degenerating decidua, and the Smiths⁴ state that this tissue substance is akin to Menkin's "necrosin". Whether this fibrinolysin (or fibrinogenolysin) is a proteolytic enzyme released directly from tissue itself or whether there is an activation of fibrinolysin or an inhibition of antifibrinolysin remains to be determined. In any event, the work of the Smiths offers a new and promising approach to the problem of the etiology of toxemia of pregnancy, and it has shed light on the obscure and difficult subject of fibrinolysis in general.

It is apparent that the coagulative defect is not the whole story in this hemorrhagic diathesis. In the case reported above, there was severe vascular damage associated with spontaneous bleeding from mucous membranes and into the skin without evidence of thrombocytopenia. It has long been claimed that the toxin in toxemia of pregnancy acts on the blood vessels.¹⁸ The Smiths⁴ also state that the toxin from the decidua is a vascular toxin as well as a proteolytic enzyme. As suggested by Williams¹⁹ twenty-five years ago, there is a striking analogy between the activity of this type of toxin and certain snake venoms having toxic vascular and proteolytic effects.

From a practical standpoint, if similar cases are encountered, administration of large amounts of fibrinogen (as Fraction I, Cohn), to restore the coagulability of the blood and the rapid removal of the uterus with its presumably toxic contents, may be, as it seemed in the case reported above, a life-saving procedure.

SUMMARY AND CONCLUSIONS

A case of hemorrhagic diathesis in pregnancy with separation of the placenta is described. The patient had none of the usual manifestations of toxemia of pregnancy but had a bleeding disorder

characterized by spontaneous bleeding from the gums and into subcutaneous tissues and incoagulability of the blood.

Studies on the blood revealed a total lack of fibrinogen as the cause of the clotting defect.

Administration of a large amount of fibrinogen (Fraction I, Cohn) intravenously was followed by a return of the clotting time to normal, and removal of the uterus was accomplished, with recovery of the patient.

Suggestive evidence of a lack of an antifibrinogenolysin was noted in experiments carried out on the plasma of the patient. However, a definite fibrinolytic effect was not established in the serum, plasma or whole blood. The failure to demonstrate a fibrinolysin may have been due to technical difficulties and does not necessarily rule out the presence of this factor.

The concept of a toxin arising in the decidua capable of exerting a toxic effect on the blood vessels, as well as having a proteolytic activity, gains support in some measure from the findings in this case.

We are indebted to Drs. O. W. Smith, G. V. S. Smith and L. K. Diamond for their advice and help.

of nitrate methemoglobinemia if no history of nitrate ingestion is obtainable, it is incumbent on the physician to ascertain whether or not well water of high nitrate content has been ingested, the cyanosis is described as an unusual grayish-brown color, the blood in methemoglobinemia is generally described as chocolate brown, brownish red or brownish black (hemolysis does not occur), blood transfusion frequently intensifies the cyanosis by enhancing the formation of additional methemoglobin, and chemical analysis of blood demonstrates nitrites

Therapeutic Rationale

A certain percentage of patients with minimal cyanosis and symptoms will recover without therapy after withdrawal of the toxic agent. Wallace,⁵ however, likens the methemoglobinemia following nitrate ingestion to the effects of rapid hemorrhage and that of enterogenous cyanosis and aniline poisoning to the effects of slow blood loss. The most urgent therapy is therefore required in cases of more advanced nitrate methemoglobinemia, and the critical period is the first twelve hours.

The treatment of choice in severe cases is the use of an agent that will hasten reconversion of methemoglobin to hemoglobin. Thionin and methylene blue are two such agents. Ascorbic acid and niacin possess the same property but act more slowly. Hence, they are more applicable to cases of methemoglobinemia due to aniline, sulfanilamide and plasmochin. Methylene blue catalyzes the physiologic reduction of methemoglobin by the body. According to Wendel,⁸ after administration in dilute solution, methylene blue is converted to the leuko or reduced form of dye by certain cellular enzymes in the red blood cell and other body cells. According to Hauschild,²⁹ who reported on the effectiveness of thionin and methylene blue (tetramethyl thionin hydrochloride) in the treatment of methemoglobinemia, a reversible oxidation-reduction system of thionin-leukothionin is produced initially. The hemoglobin-methemoglobin system is then shifted in favor of hemoglobin. Hauschild claimed that thionin administered intravenously was effective in ten minutes. Lederer³⁰ is quoted by Ferrant⁶ as follows: "Thionin, a non-toxic, violet dye, not methemoglobin formative, has a reducing power five times that of methylene blue." Thus, the use of thionin in place of methylene blue bears investigation.

At present a rapid though brief action may be expected after the intravenous injection of methylene blue. The accepted dosage is 1 or 2 mg per kilogram of body weight injected intravenously over a period of five minutes. An effect can be expected within thirty minutes. Injection of the dye under the skin and around the vein is painful and may produce necrosis. Furthermore, too rapid injection may produce hives and severe burning of the mouth. It must be emphasized again that the dye when used

intravenously produces a rapid but brief action. Hence, it is important to supplement with oral therapy for prolonged action. Ten times the intravenous dose should be given orally at the same time and repeated once or twice to cover the critical period of anoxia. It has, moreover, been suggested that glucose in vitro transforms methemoglobin into oxyhemoglobin. We have also mentioned the favorable influence of an alkaline medium. Hence, the utilization of glucose and sixth-molar lactate solutions after the intravenous administration of methylene blue appears to be desirable.

SUMMARY

The general subject of nitrate methemoglobinemia is reviewed.

A case of bismuth subnitrate methemoglobinemia recently encountered is presented.

The mechanisms involved in the formation of methemoglobin and in the evolution of rational therapy are discussed.

The increasing number of reports of methemoglobinemia due to nitrates in well water point to the growing importance of this variety.

It is re-emphasized that the use of bismuth subnitrate as a therapeutic agent is unnecessary, unwarranted and hazardous.

CASE REPORT

D B, a 3-week-old infant with a birth weight of 4 lb, 9 oz, was discharged from the hospital on the 9th day on an Olac formula. At the age of 2 weeks he had attained a weight of 5 lb, 12 oz. Six days prior to admission diarrhea developed, and a change of formula was made. The diarrhea persisted, however, and bismuth subnitrate was administered in a compound prescription at the rate of 0.1 gm (1½ gr) every 3 or 4 hours. Medication was taken as ordered for 1 day but was withheld on the night prior to admission because of the patient's bluish color. On the following morning the color improved, and medication was resumed. That evening cyanosis became marked. The attending physician administered physiologic saline solution by hypodermoclysis and referred the patient to the hospital.

Physical examination revealed a grayish-blue cyanosis. The weight was 5 lb, 8 oz. The temperature was 98°F. Activity was normal, and there was no evidence of dehydration. The head and neck were essentially normal. The heart did not appear enlarged, its rate and rhythm were normal, and no murmurs were audible. The lungs were clear to percussion and auscultation. Except for phimosis the remainder of the examination was negative.

Urinalysis and a complete blood count were within normal limits. The blood was chocolate brown when the first specimen was drawn.

The admission diagnosis of methemoglobinemia was established after the initial withdrawal of blood for examination, though the etiology was not determined until the following day. Premature management was begun at once, and the infant was given a small blood transfusion and kept in an atmosphere of high oxygen concentration. Because respiratory difficulty was not marked, methylene blue therapy was withheld initially. This course was justified by the rapid improvement incident to the measures employed. Residual cyanosis was barely visible twelve hours after admission, and twenty-four hours after admission it had disappeared completely.

PRESENT CONCEPTS

Formation of Methemoglobin

Van den Bergh,⁷ writing on enterogenous cyanosis, stated that nitrates were converted into nitrite within the intestinal tract by bacteria, the nitrite being absorbed through the injured intestinal wall and recovered in the blood stream. Years later ZoBell²³ showed that many organisms found in the intestinal tract could change nitrate into nitrite in vitro. It is now generally hypothesized that, after the introduction of nitrate into the intestinal tract, there is normally a conversion of a portion of the nitrate into nitrite and ammonia. After absorption in greater or lesser amount, nitrite may react with hemoglobin or may be excreted by the kidney. The reaction of nitrite with hemoglobin results in the formation of methemoglobin by oxidation, ferrous ion being converted to ferric ion. The process is reversible, but reconversion to hemoglobin is slow, requiring a minimum of eight or nine hours, according to Wendel,²⁴ and longer according to other authors. Inasmuch as anoxia is the basis of the symptomatology, the crux of the problem lies in the

management of the patient during the first eight to twelve hours.

Before cyanosis due to methemoglobinemia occurs, a considerable amount of nitrite must be absorbed and retained in contact with hemoglobin. According to Wendel,⁸ methemoglobin should make up at least 10 per cent of the total blood pigment before cyanosis becomes visible. Miller⁴ quotes 3 gm of methemoglobin per 100 cc of blood as the critical figure for visible cyanosis.

Our review of the literature has uncovered many factors that play a part in the absorption of nitrite and its reaction with hemoglobin to form methemoglobin.

Chemical nature of the toxic agent. It is generally recognized that methemoglobinemia appears more quickly after nitrate ingestion than after sulfanilamide or plasmochin.⁸

Age of patient. Infants are more susceptible because of the greater frequency of gastrointestinal disturbances, the presence of a bacterial flora more favorable to nitrite production (Böhme,¹⁴) the existence of nitrate-splitting organisms high in the intestinal tract, which would facilitate the reduction of the nitrate to nitrites before the nitrate could be completely absorbed,²⁵ and possibly because of less renal efficiency in eliminating nitrites.

Mode of administration of nitrate. It has long been recognized that a more severe and prompt methemoglobinemia results from the rectal administration of nitrate (Böhme¹⁴).

Integrity of intestinal mucosa. Van den Bergh⁷ implicated the injured intestinal mucosa as a factor many years ago.

Amount of nitrate administered. The appearance of cyanosis due to methemoglobinemia is generally dependent on the amount of nitrate ingested. This was recognized by Böhme¹⁴ years ago, and substantiated by the cases of Barker and O'Hare²⁶ and Tarr.¹⁶

Renal status. Nitrite retention on the basis of renal insufficiency has been implicated by Tarr.¹⁶

Rapidity of passage through the intestinal tract. Incomplete reduction of nitrate to ammonia may be the result of rapid passage through the intestine with the intermediate nitrite present in greater quantity near the absorbing surface of the intestine.

pH of blood. Greenberg et al.²⁷ have shown that the conversion of hemoglobin to methemoglobin in the presence of nitrite occurs more rapidly in an acid medium. Furthermore, Marshall and Marshall²⁸ lessened the symptoms of nitrite poisoning experimentally by intravenous administration of sodium carbonate or bicarbonate.

Diagnosis of Methemoglobinemia

The diagnosis of methemoglobinemia with scientific certainty is made only by spectroscope or spectrograph. The average physician, however, will rely on the following points to establish a diagnosis

of nitrate methemoglobinemia if no history of nitrate ingestion is obtainable, it is incumbent on the physician to ascertain whether or not well water of high nitrate content has been ingested, the cyanosis is described as an unusual grayish-brown color, the blood in methemoglobinemia is generally described as chocolate brown, brownish red or brownish black (hemolysis does not occur), blood transfusion frequently intensifies the cyanosis by enhancing the formation of additional methemoglobin, and chemical analysis of blood demonstrates nitrites

Therapeutic Rationale

A certain percentage of patients with minimal cyanosis and symptoms will recover without therapy after withdrawal of the toxic agent. Wallace,⁵ however, likens the methemoglobinemia following nitrate ingestion to the effects of rapid hemorrhage and that of enterogenous cyanosis and aniline poisoning to the effects of slow blood loss. The most urgent therapy is therefore required in cases of more advanced nitrate methemoglobinemia, and the critical period is the first twelve hours.

The treatment of choice in severe cases is the use of an agent that will hasten reconversion of methemoglobin to hemoglobin. Thionin and methylene blue are two such agents. Ascorbic acid and niacin possess the same property but act more slowly. Hence, they are more applicable to cases of methemoglobinemia due to aniline, sulfanilamide and plasmochin. Methylene blue catalyzes the physiologic reduction of methemoglobin by the body. According to Wendel,^{8, 24} after administration in dilute solution, methylene blue is converted to the leuco or reduced form of dye by certain cellular enzymes in the red blood cell and other body cells. According to Hauschild,²⁹ who reported on the effectiveness of thionin and methylene blue (tetramethyl thionin hydrochloride) in the treatment of methemoglobinemia, a reversible oxidation-reduction system of thionin-leukothionin is produced initially. The hemoglobin-methemoglobin system is then shifted in favor of hemoglobin. Hauschild claimed that thionin administered intravenously was effective in ten minutes. Lederer³⁰ is quoted by Ferrant⁶ as follows: "Thionin, a non-toxic, violet dye, not methemoglobin formative, has a reducing power five times that of methylene blue." Thus, the use of thionin in place of methylene blue bears investigation.

At present a rapid though brief action may be expected after the intravenous injection of methylene blue. The accepted dosage is 1 or 2 mg per kilogram of body weight injected intravenously over a period of five minutes. An effect can be expected within thirty minutes. Injection of the dye under the skin and around the vein is painful and may produce necrosis. Furthermore, too rapid injection may produce hives and severe burning of the mouth. It must be emphasized again that the dye when used

intravenously produces a rapid but brief action. Hence, it is important to supplement with oral therapy for prolonged action. Ten times the intravenous dose should be given orally at the same time and repeated once or twice to cover the critical period of anoxia. It has, moreover, been suggested that glucose in vitro transforms methemoglobin into oxyhemoglobin. We have also mentioned the favorable influence of an alkaline medium. Hence, the utilization of glucose and sixth-molar lactate solutions after the intravenous administration of methylene blue appears to be desirable.

SUMMARY

The general subject of nitrate methemoglobinemia is reviewed.

A case of bismuth subnitrate methemoglobinemia recently encountered is presented.

The mechanisms involved in the formation of methemoglobin and in the evolution of rational therapy are discussed.

The increasing number of reports of methemoglobinemia due to nitrates in well water point to the growing importance of this variety.

It is re-emphasized that the use of bismuth subnitrate as a therapeutic agent is unnecessary, unwarranted and hazardous.

rier when 1 gm of streptomycin was given orally daily for twenty consecutive days Pulaski and Amspacher⁴ treated 3 cases of salmonella enteritis in infants, using a daily oral dose of 100 mg per kilogram of body weight for four to seven days, and the stool cultures became negative and remained so during a three-week follow-up period Except for these three reports, the literature on the treatment of salmonella enteritis in infancy with streptomycin has been limited
During the past year, we have had the opportunity of treating 8 patients, ranging in age from three months to three years, with large doses of streptomycin for a prolonged interval This report deals with the clinical and bacteriologic observations made in these cases

BACTERIOLOGY

Rectal swabs were obtained daily and immediately streaked by the bedside on salmonella-shigella (SS) agar and desoxycholate citrate (DC) and incubated for twenty-four hours. In addition, Kauffmann's tetrathionate broth was seeded with the rectal swab and subcultured on SS plates after eighteen to twenty-four hours of incubation. Colorless colonies from SS and DC mediums were subcultured into Kligler's iron agar and identification of the organisms was performed with the use of type-specific H serums*. In questionable cultures, sugar broths, examination for motility, indole formation and other biochemical identification procedures were employed. The distribution of the various types of salmonella in this series was as follows: *S. typhimurium*, 3 cases, *S. oranienberg*, 2 cases, and *S. meunchen*, *S. manhattan* and *S. anatis*, 1 case each.

It is worth while to emphasize the desirability of repeated stool-culture examinations both for diag-

droxyamine hydrochloride on the coliform inhibitory properties of the mediums itself, and this procedure was therefore abandoned.

It is well to point out that tetrathionate broth proved to be the most sensitive medium in the isolation of salmonella organisms in our 8 cases. A total of 160 stool cultures were obtained in this series (an average of 20 per patient), of which 78 were positive for salmonella. Of these, 73 specimens yielded salmonella in tetrathionate broth, 42 on desoxycholate citrate agar, and 39 on SS agar. In the majority of cultures, the organism was recovered from two or all three mediums simultaneously. In 33 out of 78 positive cultures, however, salmonella was isolated from only one culture medium. Tetrathionate broth exclusively yielded a positive culture in 28 cases, whereas positive cultures were isolated solely on SS agar in 3 specimens and desoxycholate citrate in 2. This serves to emphasize the desirability of culturing stools on all three mediums simultaneously, in view of the fact that no single medium yielded salmonella on all

nosis and for follow-up purposes even with the selective mediums now available. The latter permit the detection of a small number of pathogens in feces by substantially inhibiting the coliform group. However, unless repeated stool examinations are performed during and after treatment with streptomycin, abortive "cures" may be reported.

Hydroxyamine hydrochloride (1:300), adjusted to a pH of 6.0, was incorporated in some control SS plates in an attempt to neutralize the inhibitory effect of the streptomycin excreted in the stool. However, the plates showed definite overgrowth with *Escherichia coli*, indicating a vitiating effect of hy-

positive stool specimens. If only one medium is to be seeded at the bedside for follow-up purposes in cases of proved salmonella infection, tetrathionate broth would undoubtedly be the most useful one to use.

DOSAGE AND MODE OF ADMINISTRATION OF STREPTOMYCIN

The lack of response of salmonella infections to smaller doses of streptomycin in Seligmann's series prompted us to use a considerably larger dosage ranging from 0.8 to 4.8 gm a day orally, with an average of 2.4 gm daily. The drug† was administered for an interval ranging between eight and

*We are indebted to Dr. Erich Seligmann, of the National Salmonella Typing Center, New York, and to Drs. H. Carlquist and L. R. Kohn of the Army Medical Center, Washington, D. C. for confirmation and final identification of the organism by the use of group-specific O serums.

†Kindly supplied as syrup of streptomycin (50 mg per cubic centimeter) by E. R. Squibb and Sons. This preparation was readily accepted and well tolerated by all the patients.

MEDICAL PROGRESS

SURGERY IN CHRONIC ARTHRITIS

JOHN G KUHN, M.D.*

BOSTON

SURGERY is employed in chronic arthritis primarily to remove or to decrease deformities and disabilities that have occurred within and about the joints.¹ If adequate early medical and orthopedic care is given, almost all disability can be prevented in chronic arthritis, and much later surgery can be avoided.² If the joints that show swelling, muscular spasm and pain are splinted to relieve muscular spasm, in a position as near to full extension as they can comfortably be placed, and if flexion deformity is then prevented by a part-time maintenance of this position, little deformity will develop. Weakness in the supporting musculature must be prevented by exercise and other physiotherapy. Severe crippling is usually found in the patient when these simple measures have been neglected.³

In the preceding decade attempts were made through surgical measures to cure the arthritis or to alter certain physiologic disturbances. Among the surgical measures sympathectomy⁴ for the lower extremity and parathyroidectomy⁵ were most widely discussed. For the most part the early discussions of these procedures were optimistic, but later reports were more critical and disappointing.^{6,7} Old measures were discarded and forgotten, and new ones were enthusiastically accepted every year.⁸ One procedure that is still vigorously defended⁹ — and as strongly condemned as valueless¹⁰ — is the extensive removal of so-called foci of infection. This subject was recently reviewed by Freyberg,¹¹ who concluded that if the arthritis was infectious a localized infection might be a trigger mechanism that started it. Removal of foci of infection was probably of no value in rheumatoid arthritis of long duration. Foci of infection should be attacked only as part of a broad program of treatment.

The aims of surgery in chronic arthritis are outlined by Wilson.¹² He speaks of the value of partial rehabilitation through well thought out surgical procedures followed by prolonged physiotherapy. In a similar manner Fisher¹³ states that orthopedic surgery can often prevent deformity in chronic arthritis, can correct deformity sometimes, can always improve function and can alleviate pain.

No surgical measures should be undertaken unless there is reasonable assurance that they will decrease pain or improve function. The usual indications and

contraindications were outlined succinctly fifteen years ago by Wilson and Osgood.¹⁴ The indications and contraindications need little modification. Quiescence of the arthritis, optimal general condition and good morale of the patient, adequate facilities for hospitalization and follow-up care. The patient should be emotionally stable and co-operative, with a sincere desire to get well. In most cases the operation is but one step in the restoration of articular function, rarely is function restored by the operative procedure alone. Before operation there should be several weeks of muscular re-education or at least muscle-setting exercises to teach the patient to use, as well as to strengthen, the muscles that will later move the joint or the limb.¹⁵ Operative procedures are usually valueless unless there is sufficient muscular strength obtainable to make useful function possible later. After operation a prolonged period of physiotherapy and exercises is required to get the greatest possible benefit. The surgeon should have a definite plan of rehabilitation. Usually, deformities in the upper extremity are treated before those in the lower extremity.

Surgical procedures are generally not contemplated in the treatment of chronic arthritis until one has clinical and laboratory evidence that the disease is quiescent.¹⁶ Most surgeons state that the patients have a more rapid convalescence, with fewer complications, and that exacerbations in the arthritis are much less likely to occur if surgery is delayed until the disease has become quiescent.^{17,18} It has been suggested that surgical procedures may be performed more easily if one does not wait for complete healing and quiescence of the arthritis.¹⁹ Although operation can be carried out with greater ease before bony ankylosis and severe contractures have occurred, if the disease is still active the convalescence is prolonged and a recrudescence of acute arthritis is often observed.²⁰ Moreover, after the inflammation in the joint subsides, a remarkable spontaneous improvement in function is sometimes seen. Unnecessarily radical procedures may be performed if one does not wait for the unaided recovery of function that follows quiescence of the disease. In rare cases operation is necessary in the early, acute stage of the arthritis, particularly when adduction deformity is present in both hips, to give the patient comfort or to make nursing care possible.²¹

*Instructor in orthopedic surgery, Harvard Medical School; lecturer in orthopedic surgery, Boston University School of Medicine; chief of surgical and orthopedic staffs, Robert Breck Brigham Hospital.

fifteen days, with an average of eleven and three-fifths days per patient. Each patient received an average of 28 gm of streptomycin orally during the course of therapy. In spite of these large doses, spot blood assays during treatment showed no detectable level of the drug when the oral mode of administration was used exclusively. This is in keeping with the well known fact that streptomycin is not absorbed from the intestinal tract. In 5 of the 8 cases in our series, streptomycin was simultaneously administered intramuscularly in a dose ranging between 0.4 and 0.6 gm a day.

RESULTS

The pertinent data on the eight cases are presented in Table 1. It will be noted that only 1 patient in this series (Case 6) showed salmonella to be permanently absent from the stool cultures. This infant received both oral and intramuscular streptomycin. In 6 other cases a definite inhibitory effect on both the salmonella organisms and the normal stool flora was observed during the period of drug administration, however, in spite of the large doses used, the pathogen reappeared in the stool three to eight days after discontinuation of the drug. In Case 1, in which the strain proved to be *S. manhattan*, the patient continued to have positive stool cultures throughout the course of therapy, even when 4.8 gm of streptomycin a day was administered orally. In 4 of the 5 patients who received combined oral and intramuscular streptomycin, there did not appear to be any enhancement in the efficacy of therapy or any noticeable delay in the reappearance of the salmonella organisms. It thus appeared that combined oral and parenteral administration of streptomycin was no more effective than oral administration alone. In view of the small number of cases in this series, it was not possible to say whether any particular strain of salmonella showed any significant variation in response to streptomycin therapy. None seemed to be apparent except perhaps for the undue bacteriologic refractoriness of the patient with the manhattan strain of salmonella.

It is to be noted that the streptomycin sensitivities observed in this series ranged from 4.0 to 12.5 microgm per cubic centimeter prior to institution of streptomycin therapy. Of interest was the observation that in no case was any significant increase in streptomycin resistance noted when the pathogen reappeared in the stools after termination of therapy. Thus, the failure of streptomycin in salmonella enteritis can hardly be explained on the basis of acquired resistance of the organism. Nor can it be explained on the basis of the initial resistance of salmonella since a sensitivity of 4.0 to 12.5 microgm per cubic centimeter would place the salmonella among the relatively sensitive groups of organisms susceptible to streptomycin. Experi-

mental studies on streptomycin stool levels obtained after the administration of varying doses of the drug orally to infants have been conducted in our laboratory during the past several months, and it has been found that with doses ranging from 0.2 to 0.4 gm every four hours, the streptomycin stool levels ranged between 10,000 and 20,000 microgm per gram of dried feces. To a first approximation, this was the dosage used in the present series of salmonella enteritis. Thus, the sensitivity of the salmonella organisms in these 8 cases was exceeded 1000 to 5000 times in streptomycin stool concentration, and yet streptomycin therapy was singularly disappointing. An analogous situation obtains in typhoid fever, in which streptomycin has been demonstrated to produce a marked inhibitory action against *Eberthella typhosa* in vitro and yet clinically and bacteriologically the antibiotic exerts no salutary effect against typhoid fever in human beings.

All 8 children showed an uneventful clinical improvement and were discharged from the hospital in good condition. Whether any favorable clinical effect was exerted by streptomycin on the course of the disease in this series is problematic. Only 3 of the 8 cases showed any marked constitutional symptoms at the time of admission, characterized by high fever, toxicity, acidosis and dehydration. It is not unlikely that vigorous management of these symptoms per se was the significant factor in effecting a favorable outcome.

SUMMARY

Eight cases of salmonella enteritis in infants and children were treated with streptomycin in large doses. Three of the patients received the drug orally alone, whereas the other 5 were given the antibiotic both orally and intramuscularly.

In spite of the demonstrated susceptibility of the salmonella organism to streptomycin in each case, only 1 of the 8 patients was rendered permanently free of salmonella. In the other 7, an inhibitory effect on both the salmonella organisms and the normal stool flora was observed during the period of drug administration, however, three to eight days after streptomycin had been discontinued, the pathogen reappeared in the stools. No significant increase in streptomycin resistance was noted in any case.

We are indebted to Miss Sara Stevens, Mrs. Eleanor Weinstein and Miss Susan Gougé for their technical assistance.

volar side of the capsule at the interphalangeal joints permits full extension at these joints.⁴² At the hip, when flexion is present, section of the fascia lata in the upper third of the thigh is occasionally useful.

In the popliteal space and occasionally at the sides of the interphalangeal joints an outpouching or herniation of a part of the articular capsule may appear. Such swellings are usually herniations of the joint, which at the knee are sometimes called Baker's cysts.⁴⁴ Occasionally these swellings subside spontaneously or decrease with pressure dressings. If they persist or become larger, their removal is indicated. It has been suggested that some of them may be enlarged bursas at the back of the knee.⁴⁵ The treatment usually advocated is simple removal of the sac, with overlapping of the fascia or muscles across the origin of the herniation from the articular capsule. Similarly, rheumatic nodules, which appear on the extensor surface of the bones in about 20 per cent of patients with rheumatoid arthritis, sometimes become irritated and painful. When pressure comes continually upon such an area, the rheumatic nodule should be removed.

When there is persistent painful swelling of the articular capsule from excessive formation of synovial fluid, aspiration and the application of a pressure dressing are usually advised. Opinion is divided about the value of repeated aspirations either for diagnosis or for therapy.⁴⁶ Usually, only temporary relief is given. Continued hydrarthrosis at a joint is generally evidence of chronic irritation within the articular cavity.⁴⁷ If clinical or x-ray examination shows any internal derangement, a foreign body, a displaced meniscus or greatly thickened synovial tissue, an arthrotomy with the removal of the tissue causing the irritation is indicated. The articular capsule is opened through the front or back of the joint, depending upon the position of the irritating material. After removal, the hydrarthrosis usually ceases.

Synovectomy — the removal of a portion or all of the synovial membrane — still has no established indications in rheumatoid arthritis.⁴⁸ Its value has been recognized since its early description by Swett.⁴⁹ The synovial membrane is no longer removed under the mistaken idea that it may be a focus of infection. The chief indication in rheumatoid arthritis is mechanical interference with function.⁵⁰ If the swelling and thickening of the synovial membrane have been present less than a year, treatment with deep x-ray therapy may cause them to subside.⁵¹ In massive swelling that is resistant to x-ray therapy or has been present for a long time synovectomy is generally required. The usual technique is to remove the synovial membrane as completely as possible through a long parapatellar incision. No tourniquet is used, but hemostasis is controlled with the electrocautery.⁵² Degenerated semilunar cartilages and interarticular ligaments must usually be removed also at the knee joint. Partial synovectomy is sometimes required at the

elbow joint when the thickened tissue interferes with extension. Removal of the synovial membrane on both sides of the olecranon and from the olecranon fossa is usually adequate. Adhesions form quickly after synovectomy if motion cannot be started soon and usually account for most of the poor results.⁵³ Cellophane and thin nylon membrane have been used over the suprapatellar space with some benefit to prevent adhesions after synovectomy.⁵⁴ Where there is great destruction of the articular cartilages in addition to the thickened synovial membrane, synovectomy is usually not helpful, arthroplasty or arthrodesis is generally advocated.

Osteotomy — the cutting of a bone to provide a better position for function — is indicated occasionally in the treatment of arthritis.⁵⁵ When a joint is stiff the surgeon must decide whether function will be served better by the formation of a new joint or by leaving the joint stiff, with the limb placed in the best position for function. At the wrist and finger joints, and usually at the tarsal joints, a stiff joint in a good position is considered to be the most satisfactory procedure. When the wrist joint has been destroyed, osteotomy is advocated followed by fusion in about 30° of dorsiflexion. At the interphalangeal joints when the joint is ankylosed or seriously deformed, osteotomy is carried out through the joint. After osteotomy the joint is held in 30 to 40° of flexion with fine Kirschner wire until the joint becomes solidly fused.⁵⁶ This gives a much more useful finger than an arthroplasty, which always causes lateral instability at the interphalangeal joints. Osteotomy has been mentioned at the metacarpophalangeal joint to correct severe subluxation and ulnar deviation. Here the distal end of the metacarpal bone is trimmed off squarely. Occasionally the proximal end of the proximal phalanx must be also reshaped.⁵⁷ Resection of the outer part of the acromion — "acromioplasty" — has been advocated to lessen pain and improve motion at the limited arthritic shoulder joint.¹⁹ Improved motion and lessening of pain at this joint have been reported.

During the past few years attempts have been made to correct the fixed anterior bowing of the spine by osteotomy.⁵⁷ Osteotomy is performed in the lumbar spine to improve the position of the dorsal and cervical regions of the spine in anterior flexion. This is a very common late deformity in rheumatoid spondylitis. Osteotomy is usually performed through the pedicles and articular facets in the lumbar region. The lumbar spine is then hyperextended, and a surgical fusion is performed to hold the lumbar spine permanently in this position.⁵⁸ Several varying surgical techniques have been reported.⁵⁹

Arthrodesis, the operative fusion of a joint in a useful position, is rarely employed in the treatment of rheumatoid arthritis. When a joint is severely damaged the natural tendency of the disease is to heal the lesion with fibrous or bony ankylosis of the

The avowed purposes of surgical treatment in chronic arthritis have been given as follows²² to make a diagnosis, to relieve pain, to correct or to improve a deformity, and to obtain motion in a stiff joint. Usually, diagnosis is certain long before operation is contemplated. When there are unusual features or if tuberculosis is suspected, examination of articular tissues²³ or occasionally of regional lymph nodes, may be of value²⁴. Sometimes in monarticular arthritis when there is little change and no progression to other joints, arthrotomy with pathological examination of articular tissue may be necessary for the making of a diagnosis²⁵.

Operations and other procedures to relieve pain are palliative only. They do not influence the course of the arthritis or improve the impaired function. Yet they are at times most welcome to the sufferer from constant pain in the joints. Such procedures consist chiefly of injections about major nerves or into the periarticular tissues about an affected joint²⁶. Rarely are sensory nerves that supply the joint cut. Occasionally, the surgical stiffening of a painful joint is carried out, pain being relieved by the stopping of all motion²⁷.

Most surgical treatment in chronic arthritis is carried out for the correction of deformities. Manipulations, lengthening of contracted soft tissues and osteotomies are the procedures that are most frequently employed²⁸. Less than 5 per cent of the cases of rheumatoid arthritis progress to the ankylosis of joints, some degree of articular damage is the usual end result. The procedures available to improve motion in a stiffened joint are osteotomy, arthroplasty and resection²⁹. Although the surgical indications for the correction of disabilities in both rheumatoid arthritis and osteoarthritis are similar, it is better for the sake of clarity to review them separately.

RHEUMATOID ARTHRITIS

Manipulation — the stretching of contracted soft tissues about a joint with the patient anesthetized — has been discussed frequently³⁰. According to Lloyd Williams,³¹ it is of value in quiescent disease to correct mild deformity and to increase motion by stretching or rupturing adhesions and by stretching shortened muscles and fascia. It should be employed with caution in quiescent disease. It may light up a quiescent inflammation³². Because the bones in chronic arthritis do not have normal strength and break easily, great care must be exercised in carrying out manipulations³³. The usual technic is to bring the distal portion of the limb first into greater flexion and then to extend it slowly. If full correction is considered unwise at the first attempt, the manipulation can be repeated as soon as the soreness caused by the first manipulation has subsided. After manipulation the limb is held in the improved position for several days, and then physiotherapy is resumed³⁴. If no correction follows one manipulation, further

ones will be ineffective, and operative lengthening of the tight structures must usually be performed³⁵.

When soft tissues are so tight that no improvement follows corrective casts or manipulation, two useful procedures have been described for the correction of contracted soft tissues. These can be employed most effectively at the knee, and less well at the elbow or finger joints. When major surgery is considered hazardous and when there is not a great amount of bony atrophy, the contracted tissues can be stretched safely by turnbuckles attached to Kirschner wire. The Kirschner wires are drilled through the bones on the proximal and distal sides of the joint. By turning of the turnbuckles the articular surfaces are distracted, and the contractures are slowly stretched³⁶. The entire limb is usually kept in a posterior cast or in balanced traction for comfort. By this method relatively painless correction of flexion and of subluxation can be obtained in two or three weeks. This method cannot be used when the bones are extremely atrophied, for the wires will then be pushed through the bones. No pressure sores develop, nor is there extensive interfascial fibrosis, both of which are found with wedging casts and forcing apparatus. After correction has been obtained, the limb is put in a bivalved cast and physiotherapy is begun.

Immediate correction of resistant contractures in rheumatoid arthritis can be obtained by lengthening the tendons of the tight muscles and by freeing the posterior portion of the articular capsule if the general condition of the patient permits a major surgical procedure³⁷. A number of technics have been described since the early description of Silver³⁸. The simplest and most effective is that described by Wilson³⁹. The essential features of this operation are cutting of the iliotibial band and fascia lata, lengthening of the biceps femoris tendon and freeing of the posterior portion of the articular capsule. The leg is held in full extension until healing is well advanced, when active exercises are given. Walking with support is permitted in two or three weeks. When full, immediate motion of the flexion deformity stretches the popliteal vessel too much, extension is carried out gradually with changes of casts at weekly intervals. In this way there is no circulatory embarrassment in the foot, and no injury occurs to the common peroneal nerve. When the motion in the knee joint is quite limited, with considerable articular destruction, rotation osteotomy performed just above the condyles of the femur has been advocated⁴⁰. The disadvantage of this procedure is that much stiffness develops in the muscles and fascia while the osteotomy is healing, before movement can again be started in the knee⁴¹.

At the elbow joint a permanent flexion deformity can be improved by lengthening the expansions of the biceps tendon⁴². The flexion deformity at the elbow is usually not a serious disability, and operation is not often required. In the fingers, freeing the

volar side of the capsule at the interphalangeal joints permits full extension at these joints.⁴² At the hip, when flexion is present, section of the fascia lata in the upper third of the thigh is occasionally useful.

In the popliteal space and occasionally at the sides of the interphalangeal joints an outpouching or herniation of a part of the articular capsule may appear. Such swellings are usually herniations of the joint, which at the knee are sometimes called Baker's cysts.⁴⁴ Occasionally these swellings subside spontaneously or decrease with pressure dressings. If they persist or become larger, their removal is indicated. It has been suggested that some of them may be enlarged bursas at the back of the knee.⁴⁵ The treatment usually advocated is simple removal of the sac, with overlapping of the fascia or muscles across the origin of the herniation from the articular capsule. Similarly, rheumatic nodules, which appear on the extensor surface of the bones in about 20 per cent of patients with rheumatoid arthritis, sometimes become irritated and painful. When pressure comes continually upon such an area, the rheumatic nodule should be removed.

When there is persistent painful swelling of the articular capsule from excessive formation of synovial fluid, aspiration and the application of a pressure dressing are usually advised. Opinion is divided about the value of repeated aspirations either for diagnosis or for therapy.⁴⁶ Usually, only temporary relief is given. Continued hyarthrosis at a joint is generally evidence of chronic irritation within the articular cavity.⁴⁷ If clinical or x-ray examination shows any internal derangement, a foreign body, a displaced meniscus or greatly thickened synovial tissue, an arthrotomy with the removal of the tissue causing the irritation is indicated. The articular capsule is opened through the front or back of the joint, depending upon the position of the irritating material. After removal, the hyarthrosis usually ceases.

Synovectomy — the removal of a portion or all of the synovial membrane — still has no established indications in rheumatoid arthritis.⁴⁸ Its value has been recognized since its early description by Swett.⁴⁹ The synovial membrane is no longer removed under the mistaken idea that it may be a focus of infection. The chief indication in rheumatoid arthritis is mechanical interference with function.⁵⁰ If the swelling and thickening of the synovial membrane have been present less than a year, treatment with deep x-ray therapy may cause them to subside.⁵¹ In massive swelling that is resistant to x-ray therapy or has been present for a long time synovectomy is generally required. The usual technique is to remove the synovial membrane as completely as possible through a long parapatellar incision. No tourniquet is used, but hemostasis is controlled with the electrocautery.⁵² Degenerated semilunar cartilages and interarticular ligaments must usually be removed also at the knee joint. Partial synovectomy is sometimes required at the

elbow joint when the thickened tissue interferes with extension. Removal of the synovial membrane on both sides of the olecranon and from the olecranon fossa is usually adequate. Adhesions form quickly after synovectomy if motion cannot be started soon and usually account for most of the poor results.⁵³ Cellophane and thin nylon membrane have been used over the suprapatellar space with some benefit to prevent adhesions after synovectomy.⁵⁴ Where there is great destruction of the articular cartilages in addition to the thickened synovial membrane, synovectomy is usually not helpful, arthroplasty or arthrodesis is generally advocated.

Osteotomy — the cutting of a bone to provide a better position for function — is indicated occasionally in the treatment of arthritis.⁵⁵ When a joint is stiff the surgeon must decide whether function will be served better by the formation of a new joint or by leaving the joint stiff, with the limb placed in the best position for function. At the wrist and finger joints, and usually at the tarsal joints, a stiff joint in a good position is considered to be the most satisfactory procedure. When the wrist joint has been destroyed, osteotomy is advocated followed by fusion in about 30° of dorsiflexion. At the interphalangeal joints when the joint is ankylosed or seriously deformed, osteotomy is carried out through the joint. After osteotomy the joint is held in 30 to 40° of flexion with fine Kirschner wire until the joint becomes solidly fused.⁵⁶ This gives a much more useful finger than an arthroplasty, which always causes lateral instability at the interphalangeal joints. Osteotomy has been mentioned at the metacarpophalangeal joint to correct severe subluxation and ulnar deviation. Here the distal end of the metacarpal bone is trimmed off squarely. Occasionally the proximal end of the proximal phalanx must be also reshaped.⁵⁷ Resection of the outer part of the acromion — "acromioplasty" — has been advocated to lessen pain and improve motion at the limited arthritic shoulder joint.⁵⁸ Improved motion and lessening of pain at this joint have been reported.

During the past few years attempts have been made to correct the fixed anterior bowing of the spine by osteotomy.⁵⁷ Osteotomy is performed in the lumbar spine to improve the position of the dorsal and cervical regions of the spine in anterior flexion. This is a very common late deformity in rheumatoid spondylitis. Osteotomy is usually performed through the pedicles and articular facets in the lumbar region. The lumbar spine is then hyperextended, and a surgical fusion is performed to hold the lumbar spine permanently in this position.⁵⁸ Several varying surgical techniques have been reported.⁵⁹

Arthrodesis, the operative fusion of a joint in a useful position, is rarely employed in the treatment of rheumatoid arthritis. When a joint is severely damaged the natural tendency of the disease is to heal the lesion with fibrous or bony ankylosis of the

joint. When this ankylosis is unsound, arthrodesis may be indicated.⁶⁰ But most patients prefer either the use of apparatus to avoid pain or an operative procedure that will leave them with motion at the joint.^{61 62} Arthrodesis is justified as a temporary expedient to relieve pain rapidly at the knee or hip joint. This is performed by the use of nails or wire driven across the joint. Such immobilizing material can later be removed, and an operation to obtain motion can be performed when the arthritis becomes quiescent. In many cases, after arthrodesis, more arthritis and sprain have been observed in the joints above and below the arthrodesis. In the foot, arthrodesis of the tarsal joints and of the ankle joint in the best position for walking are useful procedures when these joints are hopelessly damaged and cause pain.⁶³ Usually, nature fuses these joints in the course of the arthritis and the surgeon's task is to keep the foot in good weight-bearing position until fusion takes place. For deformities in the anterior portion of the foot the procedures used for the treatment of severe static deformities are advocated.

Arthroplasty — the formation of a new, movable joint after ankylosis from rheumatoid arthritis — has been called the essence of patchwork surgery. Well fitting articular surfaces can be formed without difficulty in the major joints, but the bones frequently do not remain as they had been shaped.⁶⁴ The osteoporotic bones and the atrophied muscles, which are frequently found in the later stages of rheumatoid arthritis, are poor materials to work with. With weight bearing and with motion the ends of the bones often become greatly distorted. This distortion is much less when plastic or metallic molds are fitted over the articular surfaces.⁶⁵ Orthopedic procedures have been reported in most of the major joints, but useful joints, after arthroplasty, have been reported chiefly at the elbow, the hip and the knee.

At the elbow joint a number of procedures have been described from wide resection to arthroplastic procedures. All these procedures usually give a movable elbow joint, but an arthroplasty gives a somewhat more stable elbow.⁶⁶ Usually, fascia lata is interposed between the bone ends. A wide range of painless motion is reported, but normal strength and stability are not regained. At the knee joint, fascia has also been used as an interposition material to prevent reankylosis after arthroplasty. In most cases this has worn away quickly, but a small number of good results have been reported.⁶⁷ Cellophane and nylon membrane have been employed in a few cases, with somewhat greater success.²¹ In most cases a limited range of motion has been obtained after prolonged physiotherapy. Samson⁶⁸ believes that arthroplasty of the knee should be performed only rarely in rheumatoid arthritis.

At the hip joint when ankylosis has taken place arthroplasty is indicated when the patient must sit

for work. In persons who must stand, a stiff, painless hip in a good position for weight bearing is usually more satisfactory. Some satisfactory arthroplasties were obtained by the use of fat or fascia as interposition materials, but in most cases these substances quickly degenerated under pressure and reankylosis occurred.⁶⁹ Metallic or plastic cups that fit over the femoral head have withstood distortion and have given much more useful hip joints.⁷⁰

Arthroplasties have been reported on practically all the major joints of the body. A number of operations on the fingers and toes have been described. But for the most part, except for the elbow, the hip and the knee, these offer little gain in function. Rarely is arthroplasty required at the temporomandibular joint, ankylosis here is rare but some limitation of motion is common.⁷¹ A number of successful arthroplasties on this joint have been reported.

OSTEOARTHRITIS

Osteoarthritis rarely produces serious deformity, and, consequently, does not require surgical treatment very often. However, in persons who do heavy labor and in others with some malformation in a weight-bearing joint, severe pain and deformity are sometimes seen with osteoarthritis. Operation is performed more often for the relief of pain than for any other reason in osteoarthritis. Although most persons who seek surgical treatment are past middle age they stand surgical procedures surprisingly well. The indications and prerequisites are the same as those for rheumatoid arthritis.¹² Whereas there is no active inflammatory process or quiescence of the disease in osteoarthritis, any inflammation from mechanical insult should have subsided before operation is undertaken. More surgical procedures are performed for disability at the hip and knee than for any other joints.

Manipulation under anesthesia is performed in osteoarthritis for the joints of the cervical spine, the shoulder, the hip, the knee and the foot. It has been suggested that impingement and irritation of cervical nerves can be relieved at times by gentle manipulation of the cervical spine. Osteoarthritis of the shoulder is frequently associated with fascial and capsular irritation and subsequent adhesions. These can be released, and freer and less painful motion may result. Mennell⁷² has demonstrated that improved motion may follow manipulation of the hip in osteoarthritis if there is not much deformity of the femoral head. Sometimes, repeated gentle manipulations remove almost all disability. Manipulation is rarely required at the knee. If there is much limitation of extension it is usually the result of an internal derangement, and arthrotomy is often required.⁷² A rigid valgus deformity of the foot is occasionally seen in osteoarthritis. Manipulation and fixation in a corrected position in a plaster cast, with later a support to the foot, often relieve this

Neurectomy

Cutting of the obturator nerve has been said to relieve most of the pain in osteoarthritis of the hip joint. The sensory distribution to the hip joint is extensive, but most of the anterior distribution comes from the obturator nerve.⁷³ This is cut within the pelvis just before the nerve enters the obturator foramen. Sometimes, for completeness, fibers coming to the posterior capsule with the nerves to the external rotators of the hip are also cut. This operation, which is not a serious surgical procedure, is usually reserved for elderly persons in whom relief of pain, rather than improvement in function, is the chief desideratum. Denervation has been reported in other joints, but here it has as yet not passed the experimental stage.

When there is much limitation of motion from osteoarthritis in early middle age, various plastic procedures have been described to remove the bony overgrowth and to improve motion. Cheilotomy gives relief until the re-formation of overgrowth again limits motion about the joint. Partial cheilotomy and acetabuloplasty⁷⁴ give temporary relief only. At the hip, arthroplasty⁷⁵ is useful in monoarticular disease (so-called secondary osteoarthritis in younger persons). At the knee a partial synovectomy and trimming of bony overgrowth have lessened pain and increased motion.^{62, 76}

Removal of the patella when it was markedly overgrown and interfered with function was advocated by Berkheiser.⁷⁷ Subsequent reports have been conflicting,⁷⁸ but most recent reports and my own experience suggest that the patella is essential for the normal mechanics of extension at the knee.⁷⁹ Plastic procedures on the patella seem to give a better functional result than complete removal.

Degeneration of intra-articular ligaments and other structures about the joint in osteoarthritis are commonly found. At the shoulder partial or complete tears of the supraspinatus tendon are a frequent accompaniment. In the lower back, ruptures of the intervertebral disk are a not uncommon complication of osteoarthritis. Unless there is severe sciatic pain the diagnosis may be difficult. Operative removal of the extruded disk substance is sometimes required both in the cervical and in the lumbar spine. At the knee in osteoarthritis, internal derangement is often evidence of a foreign body or a displaced meniscus. Relief of pain and surprising recovery of function often follow arthrotomy.

At various times attempts have been made to improve the circulation about the joint with the mistaken idea that in this way a halt could be made in the degenerative process and that a regression in the periarticular overgrowth might result. One of the earliest means employed was forage,⁸⁰ a drilling into the bone to provide new channels for vascularization. This has been carried out at the hip joint more often than any other joint. Here drill holes were

bored into the femoral neck. More recently, transplantation of available muscle, chiefly the vastus externus, has been made into the femoral neck to accomplish the same end.⁸¹

When there is much deformity from osteoarthritis at any joint a number of simple and helpful procedures have been reported to correct such a deformity.⁸² One of these is osteotomy. Although this procedure has been used on rare occasion at the acromioclavicular joint, the elbow joint and the wrist, it has been employed most extensively at the hip joint. The operation that has received the most attention has been the intertrochanteric osteotomy of McMurray.⁸³ This procedure is not particularly shocking. By it, adduction and external rotation of the leg can be fully corrected, and the femoral shaft can be displaced inward, changing the weight thrust a little and making for increased stability of the joint. Such procedures are usually reserved for patients in later middle life when correction of deformity is desired rather than increase in articular motion.⁸⁴

In the elderly patient many surgeons recommend complete stiffening of the painful joint for the relief of pain. One of the simple, earlier methods for obtaining this end was simple nailing of the hip through the neck into the acetabulum.⁸⁵ It was found that many hips with osteoarthritis failed to become ankylosed by this means. A number of more extensive procedures, some of them carried out in two stages, have been reported.⁸⁶

Operative removal of the extruded disk substance is sometimes required both in the cervical and in the lumbar spine. At the knee in osteoarthritis, internal derangement is often evidence of a foreign body or a displaced meniscus. Relief of pain and surprising recovery of function often follow arthrotomy.

At various times attempts have been made to improve the circulation about the joint with the mistaken idea that in this way a halt could be made in the degenerative process and that a regression in the periarticular overgrowth might result. One of the earliest means employed was forage,⁸⁰ a drilling into the bone to provide new channels for vascularization. This has been carried out at the hip joint more often than any other joint. Here drill holes were

bored into the femoral neck. More recently transplantation of available muscle, chiefly the vastus externus, has been made into the femoral neck to accomplish the same end.⁸¹

When there is much deformity from osteoarthritis at any joint a number of simple and helpful procedures have been reported to correct such a deformity.⁸² One of these is osteotomy. Although this procedure has been used on rare occasion at the acromioclavicular joint, the elbow joint and the wrist, it has been employed most extensively at the hip joint. The operation that has received the most attention has been the intertrochanteric osteotomy of McMurray.⁸³ This procedure is not particularly shocking. By it, adduction and external rotation of the leg can be fully corrected and the femoral shaft can be displaced inward, changing the weight thrust a little and making for increased stability of the joint. Such procedures are usually reserved for patients in later middle life when correction of deformity is desired rather than increase in articular motion.⁸⁴

In the elderly patient many surgeons recommend complete stiffening of the painful joint for the relief of pain. One of the simple, earlier methods for obtaining this end was simple nailing of the hip through the neck into the acetabulum.⁸⁵ It was found that many hips with osteoarthritis failed to become ankylosed by this means. A number of more extensive procedures, some of them carried out in two stages, have been reported.⁸⁶

CASE 35151

PRESENTATION OF CASE

A seventy-year-old farmer was admitted to the hospital because of a very productive cough.

For several years he had a chronic cough, most severe in the morning, when he raised moderate amounts of whitish sputum. He was in otherwise good health for his age. Five months before admission the cough increased in frequency and productivity, so that at the time of admission he was raising about half a cupful of yellowish and occasionally blood-stained sputum each day. Progressive lack of appetite, weight loss and weakness appeared. A physician performed an x-ray examination eight days before entry. Penicillin therapy was given. The patient was told that he had a lung abscess that was increasing in size despite chemotherapy, and he was transferred here.

On admission he appeared weak and emaciated but in no acute distress. The tongue was red and smooth, he was edentulous, with an upper plate. The trachea was in the midline, and there were dullness to percussion and decreased breath sounds in the region of the right fourth rib posteriorly. There was no change in tactile fremitus. The heart was within normal limits. A small, indirect hernia was present in the right inguinal region. The prostate was twice the normal size but not hard. The blood pressure was 150 systolic, 90 diastolic.

The urine had a specific gravity of 1.026 and gave a + test for albumin. The white-cell count was 16,800, with 77 per cent neutrophils, 8 per cent lymphocytes, 8 per cent monocytes and 7 per cent eosinophils. The serum total protein was 6.06 gm per 100 cc, chloride 105 milliequiv per liter, and nonprotein nitrogen 24 mg per 100 cc. The prothrombin time was 23 seconds (control, 16 seconds).

An electrocardiogram on the fifth hospital day showed a normal rhythm at a rate of 75, with the PR interval equal to 0.15 second and normal axis. The T waves were low upright in Leads 1, 2 and 3, with upright TV_1 , V_1 and V_2 and flat T_{AVL} and low upright T_{AVF} .

X-ray examination of the chest showed an increased anteroposterior diameter. Both leaves of

the diaphragm were low, and fluoroscopically were seen to be limited in their excursion. The lung fields were bright. In the apex of the right lower lobe lying posteriorly in contact with the chest wall was a rounded shadow, 7 cm in diameter, in which there was a fluid level. The shadow was slightly lobulated in contour, and the upper portion of the wall of the cavity was seen to be irregular along its inner wall (Fig 1). There was little or no reaction in the surrounding lung. The sputum was negative for acid-fast organisms, and cytologic examination for tumor cells was reported as "doubtful." Bronchoscopy demonstrated no abnormalities except that the dorsal division of the lower lobe was somewhat reddened, and a thin, whitish, mucoid secretion exuded from it. There was no fixation or deformity here.

FIGURE 1

or elsewhere. On the ninth hospital day a right lower lobectomy was performed. Toward the end of the operation the blood pressure fell to 90 to 100 systolic, 50 diastolic. At the end of the operation the blood pressure was up, and the condition was good. A blood transfusion of 2000 cc was given.

Twelve hours later the patient's general condition seemed good, although there was a hypotension (blood pressure of 80 systolic, 40 diastolic), without rise in pulse. Fourteen hours after operation the blood pressure dropped to 60 systolic, 40 diastolic, and a marked bradycardia (rate of 44) appeared. An electrocardiogram showed an irregular auricular and ventricular rhythm, with auriculoventricular dissociation and prolonged QRS time. Many artifacts obscured the tracing, but the T wave in Lead 1 appeared upright, with a low upright T wave in Lead 2, inverted T wave in Lead 3 and depressed

ST segments in Leads CF₁ and CF₄, with probably upright T waves in Leads CF₁ and CF₄. He died thirty-six hours after the operation

DIFFERENTIAL DIAGNOSIS

DR LOWREY F DAVENPORT This is the recurrent problem of differential diagnosis between infection and tumor. Did this man have a simple lung abscess? Did he have an abscess that developed secondarily to bronchial obstruction, or was this a primary tumor in the lung with beginning central necrosis to account for the symptoms? I should like to see the x-ray films

DR STANLEY M WYMAN The posteroanterior and lateral views show this well rounded, quite discrete shadow of increased density far posteriorly in the right chest and somewhat medially, and it seems to be close to the chest wall. There is a clearly defined fluid level within this round shadow. The wall of the shadow itself is thickened, and its inner contour is shaggy and irregular as the record states. This is a Bucky film taken for rib detail and shows the ribs and the spine in this area to appear within normal limits. The heart shadow is a little prominent in the region of the left ventricle, and the aorta is quite tortuous. The chest generally is emphysematous.

DR DAVENPORT We have to explain, then, a localized lung lesion in the dorsal portion of the right lower lobe. The differential diagnosis here is between infection and tumor. I believe, in a man of this age with this large an abscess cavity, who had a sputum negative for tubercle bacilli, that we can with reasonable certainty rule out the consideration of tuberculosis. The differential diagnosis lies between a simple lung abscess and an abscess that developed in a necrotic tumor mass. The localization of the abscess in the dorsal portion of the lower lobe is not uncommon for a simple lung abscess. However, we have nothing in the background of this patient to explain the appearance of lung abscess. Presumably his teeth had been removed many years previously, and there is nothing in the history as given to suggest any possible etiologic agent for a lung abscess. Lung abscesses as discrete as this usually show surrounding pneumonitis unless there has been intensive chemotherapy. Rarely in a lung abscess do we see such a sharply demarcated lesion as presented here. Most tumors arising in the bronchial tree in the periphery of the lung of a solitary nature, and of this size, are adenocarcinomas. In such a situation these tumors frequently outgrow their blood supply and show a central necrosis. A Papanicolaou stain on the material taken from the patient's sputum showed a doubtfully positive test. I assume that the material from this tumor was so necrotic that even though he was raising tumor cells, it might be difficult to recognize them under the microscope. The remain-

ing findings at bronchoscopy are of no significance in a tumor situated as far posteriorly as this tumor was. We are given the symptom of chronic cough for several years. Apparently, that was the type of morning cough that a man who has spent seventy years of his life in New England is reasonably entitled to. The cough that became alarming and troublesome had been present for only five months. Cough of five months' duration is not unusual with a tumor such as this is, with a central necrosis. I would think, then, that the lung picture was that of a bronchiogenic tumor, probably an adenocarcinoma, undergoing central necrosis.

I think that secondarily it would be of some interest to try to puzzle out why he died within thirty-six hours of operation. When a patient dies within thirty-six hours of a major operation such as a lobectomy we should like to know, first, whether or not a suture had slipped following cough as he began to rouse from the anesthesia. However, with the drop in blood pressure the pulse did not become elevated. This bradycardia excludes the possibility of blood loss as explanation for the low blood pressure and symptoms twelve hours after operation. Over and over again we get confused between the differential diagnosis of pulmonary embolism and coronary occlusion. Pulmonary embolism may give a definite pattern of symptomatology. In a certain percentage of cases there are suggestive changes in the electrocardiogram. No changes diagnostic of pulmonary embolism were present in the second electrocardiogram, but the tracings suggest coronary occlusion. The secondary shock in a man of seventy who has arteriosclerosis of the coronary arteries may cause acute coronary occlusion. Whatever the trigger mechanism that precipitated the cardiac episode, a man who develops a sharp drop in blood pressure without evidence of blood loss, a cardiac rate of 42 and complete dissociation by electrocardiogram of auricular and ventricular rhythm must have a profound disturbance of cardiac conduction mechanism, presumably on the basis of coronary occlusion.

My final diagnosis is primary carcinoma of the bronchus and death thirty-six hours following operation from an acute coronary occlusion.

DR DONALD S KING Can you distinguish between abscess and tumor by the thickness of the wall and the shaginess of the wall?

DR WYMAN No, not in all cases. I think, as Dr Davenport pointed out, that the thickness and contour of this wall together with the absence of the reaction about it, definitely favor tumor over an inflammatory process such as abscess. The two overlap, however, in certain cases and make it impossible to be certain.

DR ALFRED KRANES Knowing the tendency of these tumors to metastasize to the adrenal glands, could you consider acute adrenal insufficiency as a

possible mechanism for the hypotension following operation and the events that followed it?

DR DAVENPORT I do not think I would consider it as a probability I might consider some such mechanism in the development of the low blood pressure, in the absence of anything else to explain it. We have no evidence of adrenal disorder prior to operation, and it seems hardly likely that he developed such a condition within thirty-six hours of operation.

DR KRANES Except that this degree of surgery might be enough to throw a person into acute adrenal insufficiency. He had no previous sign of it, and I do not think that one can make the diagnosis. It is just speculation.

DR EDWARD B. BENEDICT I think it is worth pointing out why we did a bronchoscopy on a tumor that was obviously quite peripheral and beyond the reach of the bronchoscope. We did it because sometimes we can find tumor cells in the bronchoscopic washings when we have negative cytologic findings in the sputum.

DR BENJAMIN CASTLEMAN In this case a cytologic examination of the washings showed definite tumor cells. Then Dr. Soutter took over.

DR LAMAR SOUTTER There is one interesting point about the lack of surrounding pneumonitis. This patient had been on large doses of penicillin for a month prior to entry so that one could expect less pneumonitis than is usually found with an abscess. It might be questioned why anyone would do lung surgery on a patient of seventy who had emphysema. If he had had a benign abscess it could have been drained, which would have been a simpler procedure than a lobectomy. But because we believed that he had a malignant lesion and was going steadily downhill, we thought it reasonable to do a lobectomy on this man to rid him of his sepsis. This procedure for a peripheral tumor has a reasonable chance of effecting a cure and is much safer than a pneumonectomy in older patients. We believed that he would withstand such a procedure but not a pneumonectomy. He was seen by a cardiologist, who thought that the heart was all right. The operation was long, and the dissection was difficult because of the inflammatory changes around the hilus of the lung. Toward the end he had a sudden fall of blood pressure accompanied by bradycardia. We discussed with the anesthetist at that time the possibility of adrenal insufficiency, which Dr. Kranes mentioned. We gave him neo-synephrine, to which he had a favorable response. Postoperatively, when he again had a fall of blood pressure with bradycardia we thought of hemorrhage. But he had only a moderate amount of bloody fluid coming from his chest drainage tube. We gave him another transfusion, which did not affect his blood pressure. His bradycardia persisted. The cardiologist suggested that it was probably

on the basis of myocardial failure. That is why an electrocardiogram was taken.

DR RICHARD CLARK There were two tracings done before the final episode. These are of value, primarily as showing nothing of great significance and as serving as a base line. This is the one taken after the operation, and it does show more than is described in the protocol. There is a distinct depression of the ST segment in Lead 1 of approximately 1 mm, a distinct elevation of the ST segment in Lead 2 of approximately 2 mm and distinct elevation of the ST segment take off in Lead 3, whereas in Leads CF₁ and CF₂ there is significant depression of the ST segments. The T waves themselves are somewhat obscured by the superimposed P waves going with the auriculoventricular dissociation. I think this tracing is entirely consistent with an acute posterior myocardial infarction, which also involves the conduction system.

CLINICAL DIAGNOSES

Carcinoma of lung, right
Right lower lobectomy, recent
Coronary thrombosis
Myocardial infarction, recent

DR DAVENPORT'S DIAGNOSES

Bronchiogenic carcinoma
Acute coronary occlusion

ANATOMICAL DIAGNOSES

(Squamous-cell carcinoma of lung)
Operation lobectomy
Acute coronary thrombosis
Myocardial infarct, recent
Tuberculosis, old, bronchial lymph nodes

PATHOLOGICAL DISCUSSION

DR CASTLEMAN Dr. Soutter removed the lower lobe with a portion of two ribs to which the tumor was adherent. In the center of the lesion was a necrotic cavity surrounded by irregular and nodular, granular tumor. Microscopically it was a squamous-cell carcinoma, Grade III. The regional lymph nodes showed no metastases, but there was old tuberculosis. The final affair, both as Dr. Clark and Dr. Davenport predicted, was an acute thrombosis of the right coronary artery. This vessel supplies the interventricular septum and posterior wall, which was infarcted. Microscopical examination of the infarct showed an extensive infiltration with leukocytes, such as one sees in an infarct about two days old. It would be interesting to decide whether this infarction could possibly have occurred before the operation or just before or even during the induction of anesthesia. I do not see how we can settle from the section of the myocardium whether it was thirty-six or forty-eight hours old. Certainly, it was within

that range. The polymorphonuclear leukocytes were still well defined and had not begun to degenerate very much. The myocardial fibers themselves were granular and had lost their striations. We found no metastases anywhere in the body.

CASE 35152

PRESENTATION OF CASE

A seventeen-year-old grocery clerk was admitted to the hospital because of an abdominal mass.

The patient had been in excellent health until two months before admission, when he noted the onset of severe, gnawing pains coming on four to six hours after meals. These were confined to the left hypochondrium and relieved by food. Associated with this was regurgitation of food shortly after

episode of jaundice and clay-colored stools, both of which subsided spontaneously. The remaining past history was completely noncontributory.

Physical examination revealed a well developed young man, showing some pallor and evidence of weight loss. The cervical and axillary lymph nodes were just barely palpable. The heart and lungs were normal. There was a large, hard mass in the left hypochondrium, filling the left upper quadrant. It was slightly tender and moved with respirations. The liver edge was palpable two fingerbreadths below the right costal margin. The right testicle and epididymis were enlarged, measuring together 5 by 4 by 3 cm. There was no history of injury, and the mass was nontender. The patient stated that one month before admission he had noticed the right testicle becoming larger than the left.

The temperature was 99°F, the pulse 100, and the respirations 18. The blood pressure was 130 systolic, 88 diastolic.

The urine showed a ++ test for bile and an occasional white blood cell. The blood hemoglobin was 10 gm. The white-cell count was 8000, with 86 per cent neutrophils, 6 per cent lymphocytes, 4 per cent monocytes, 2 per cent basophils and 2 per cent immature cells. The serum nonprotein nitrogen was 26 mg., and the total protein 5.7 gm. per 100 cc., the chloride 97 milliequiv. per liter, and the prothrombin time 20 seconds (control, 15 seconds). The stool was guaiac negative.

On the fourth hospital day gastroscopy was attempted, but neither the operative gastroscope (Benedict) nor the smaller gastroscope (Schindler) passed through the cardioesophageal junction. The cardiac orifice was dilated slightly with a No. 20 Fr. bougie, but no tumor could be seen. A roentgenogram of the chest showed a fine, strand-like increase in density throughout both lung fields. There was no enlargement of the hilar lymph nodes. There was an incidental finding of an old, healed fracture of the right tenth rib posteriorly. A gastrointestinal series showed a normal esophagus. There was a large, lobulated, firm mass surrounding the stomach and apparently inside the greater wall, extending from the fundus to the pylorus. Normal mucosal folds could be seen only in the extreme portion of the fundus. There were some very thick folds along the greater-curvature side (Fig. 1). A large, apparently intraluminal ulcer, 7 cm. in diameter, was present on the lesser curvature. There was no peristalsis, and the entire stomach was rigid, fixed and unpliable. There appeared to be enlargement of both liver and spleen. On the sixth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. J. GORDON SCANNELL: I think it is of considerable interest that there was a low lymphocyte count. It may be of significance.

FIGURE 1

eating, which caused him to limit himself to a semi-liquid diet. Three weeks prior to entry a mass was found in the left hypochondrium, and at about this time he complained of the feeling of food seeming to "stick" in the region of the umbilicus. He also passed two bulky, tarry stools following which he became progressively more constipated. One week before admission the onset of low thoracic back pain, more marked at night, was noted. Despite these symptoms and a weight loss of 15 pounds, his appetite remained excellent, and he continued his usual activities, such as playing hockey in the evening. There was no malaise, hematemesis or known fever. Four years before admission he had a seven-day

Before looking at the x-ray films, which should be extremely helpful, we might review the history and see what definite leads we can get from the symptoms. Certainly, the patient had a good many symptoms involving the gastrointestinal tract. The pain, in a certain sense, could not have been more characteristic of ulcer, and he also had evidence of obstruction, although I would interpret the evidence of obstruction to be more indicative of motor disturbance of a large organ rather than obstruction distal to an organ that contracted. He did not have cramps, and he was without nausea, pain and real vomiting, although he had regurgitation of recently eaten food. He had some bleeding in the past presumably, and he certainly was anemic, which in a male patient connotes blood loss. It is interesting that he had a guaiac-negative stool in view of the fact that a large ulcer was visualized on x-ray study. He had lost weight, in spite of all this the appetite was good, which I think would be extremely unusual for a large, primary neoplasm of the stomach. The second lead, which occurs to me from the history is the evidence of retroperitoneal involvement by whatever process we are dealing with. He had low dorsal pain, worse at night, which sounds as if he had something in the retroperitoneal area high up. Secondly, there is some evidence of biliary-tract obstruction, indicated by the fact that he had some bile in the urine. We wonder a little later if he had splenic-vein obstruction, with the enlargement of the spleen. The third obvious feature is the painless, nontender, testicular tumor coming on without antecedent history of trauma and attaining significant size in a short time.

The physical signs are important. There was essential absence of peripheral lymph nodes, so that would tend to steer away from the diagnosis of lymphoma. He had a large, hard mass in the left upper quadrant. This mass moved with respirations, which, I suppose, means that it was intraperitoneal in nature, although it seems to me difficult, with a large mass that has not a great deal of inflammatory fixation, to say that is necessarily so because I think a retroperitoneal mass, if large and nodular enough and not much inflamed, could move with respirations merely from the diaphragm downward. I am impressed by the description of the testicular tumor, which was localized to the testis itself and possibly the epididymis, did not invade the adjacent structures, and did not extend up the cord.

DR JOHN M RAKER It is only fair to note that the other testicle had the same consistence and was also slightly enlarged.

DR SCANNELL I think I would rather have not known that I have to now. The testicular mass was firm but not stony hard?

DR RAKER It was quite hard.

DR SCANNELL The laboratory studies showed a lymphocytopenia, and I think that that might be indicative of low obstruction to the thoracic duct, which is one of the normal paths of the lymphocytes into the circulating blood. He had an anemia. We do not know the red-cell count, but probably do not need to. He had a ++ test for bile in the urine, unsupported by other evidence, I suppose that is indicative of some regurgitative type of jaundice. He might well have had a low-grade obstruction of the lower end of the biliary tract.

May we look at the x-ray films?

DR STANLEY M WYMAN The films of the chest show a possible minimal increase in the linear markings, but this is not very striking. I can see no localized disease in the lung fields, and the heart shadow is not remarkable. The old fracture of the right tenth rib is seen, and there is no evidence that this is pathologic. The strikingly abnormal stomach is well seen on this series of films, and the abnormality appears to extend from the extreme cardia to the immediate prepyloric region. The stomach maintains a constant contour, with very markedly thickened, irregular, possibly nodular, mucosal folds, with a tremendously large ulceration on the lesser-curvature side of the stomach, which appears to fall within the projected lumen of the stomach—at least in part. There is a suggestion, but nothing more definite, of a surrounding soft-tissue mass at several points in the stomach. The most important observation is the fluoroscopic observation that the stomach was rigid. The spleen can be faintly outlined, and it appears enlarged. The liver edge is less well visualized, and I am not so certain about the degree of possible hepatic enlargement.

DR SCANNELL Your opinion is, then, that there is an intrinsic lesion of the stomach as well as extrinsic.

DR WYMAN I can see no definite evidence of an extrinsic lesion of the stomach, and I would call this intrinsic disease in the stomach itself, a process that infiltrates the entire stomach wall from the cardia to the prepylorus.

DR SCANNELL Could it be something growing through the stomach from outside in?

DR WYMAN I do not believe so, since it involves all the organ and seems to involve it rather uniformly. With something extrinsic I would expect it to involve one portion or another primarily.

DR SCANNELL You do not believe that something arising in the peritoneal cavity on the peritoneal coat of the stomach and invading the wall could give secondary changes in the mucosa?

DR WYMAN I do not believe it could be so extensive and so uniform. I would expect it to be localized to one region or another, probably on the lesser curvature.

DR SCANNELL I am getting more and more into deep water the more help I get.

I want to go back to the testicular tumor. There is no evidence of lymphatic blockage and no evidence of lymphatic metastases. In arriving at a diagnosis it seems reasonable to assume that the patient had a malignant lesion, and I think if it were not for the testicular tumor lurking malevolently in the background, one could make a strong case for a primary lesion in the stomach. These are admittedly rare in this age group but not unheard of. If it were a malignant tumor of the stomach, it would be something along the line of the lymphoma group — lymphoblastoma or something of that nature. But we have no other evidence of lymphoma, and it is very striking that these gastric symptoms are what they are if the tumor is primary there. Therefore, at a considerable risk, I am going to admit that it might be that, but I am more impressed by the testicular swelling and I think that the testicular tumor could give rise to these symptoms as given. I suppose, before going down farther, we should mention the other organs of the left upper quadrant, — the spleen, pancreas, kidney and left adrenal gland, — but there is no specific evidence to incriminate any of these. However, testicular tumor, as I would visualize it, would have to give rise to extensive retroperitoneal metastases in the region of the root of the mesentery, in the cisterna chyli and thoracic duct, and also peritoneal metastases to account for the picture as given. Of the testicular tumors, this is not an unlikely performance for a seminoma. I am using for my authority a recent report by Friedman and Moore* of some 922 cases studied in the Army Insti-

tute of Pathology, which recorded the accumulated experience of the last war. Friedman and Moore believed they could fit testicular tumors into four groups in which seminoma was as common as any other. They tended to occur later in life. They usually were restricted in that they did not invade massively at the local site but did tend to invade the retroperitoneal area and the peritoneal lining, which seems to have occurred in this patient. Other testicular tumors, which they group as embryonal carcinomas and which include the chorionepitheliomas, tend to invade locally and metastasize to the lung or liver. This patient did not show this. He had no secondary endocrine changes such as these patients frequently show or at least have demonstrated by urinary assay. A third type, which the authors report, are teratomas. These may be either adult, in which case they are considered relatively benign, or teratocarcinoma. Teratocarcinoma merely means a teratoid tumor in which definite malignant cells can be identified. These usually metastasize by virtue of their obviously malignant elements. They also metastasize to the parenchymal organs. The adult teratoma, which is usually benign, may metastasize as a relatively adult tumor, although this is comparatively rare.

I assume that, since Dr Wyman has said that this probably was an intrinsic stomach lesion, I am displaying rank ingratitude to ignore it, but I think we can explain the picture on a seminoma, which developed massive retroperitoneal metastases in the region of the celiac axis and involved the stomach in the region of the cardia, where the stomach is really a retroperitoneal organ. The tight constriction, as it were, about the stomach would produce the secondary changes in the luminal portion.

DR ALFRED KRANES I do not quite understand why Dr Scannell ruled out lymphoma.

DR SCANNELL I believe that we cannot rule it out. We have no other lymph nodes involved, but we do have a testicular tumor that could account for the symptoms.

DR KRANES The enlargement of the spleen?

DR SCANNELL The enlargement of the spleen could have been on the basis of obstruction of the splenic vein or retroperitoneal metastases.

DR EDWARD B. BENEDECT I would bet on a primary tumor of the stomach, partly on the basis of what Dr Wyman describes and partly because when the gastroscope meets complete obstruction at

*Friedman, N. B., and Moore, R. A. Tumors of testis: report on 922 cases. *Mil Surgeon* 99:575-593, 1946.

the cardiac orifice, it usually means primary tumor of the stomach

DR RAKER The other testicle with the same consistence does not disturb you, Dr Scannell?

DR SCANNELL It disturbs me, yes

DR WYMAN Roentgenologically, this picture is most consistent with lymphoma of the stomach

DR MILFORD D SCHULZ To confuse the picture a little more, I looked at some films from this patient about an hour ago, and the stomach looks today not unlike what it did at the first examination here, after having been subjected to a period of two weeks of x-ray treatment. The patient received something like 1250 r in the region of the stomach, and there had been no demonstrable change

DR BENJAMIN CASTLEMAN This patient was operated on by a team of urologists and surgeons. Perhaps they can answer some of the questions

DR WALTER S KERR When I saw him the right testicle was twice the normal size, the left testicle was normal. Two days later the right one had grown twice the size and the left one three times the original size — a matter of a few days. We explored the right testicle and found that it was involved by a uniformly appearing tumor. Dr Moorman took over at that stage

DR HENRY D MOORMAN I explored the upper abdomen and took a biopsy from the involved wall of the stomach. The peritoneal cavity contained a large quantity of fluid, quite cloudy in appearance. The tumor seemed to arise intrinsically in the stomach in the sense that the tumor did not break out through the anterior serosal surface. We merely biopsied the anterior surface of the stomach because the whole mass was thick, and apparently all the retroperitoneal lymph nodes were involved

CLINICAL DIAGNOSES

Gastric neoplasm, ? lymphoma
Tumor of testis

DR SCANNELL'S DIAGNOSIS

Seminoma of testis, with retroperitoneal metastases and extension into stomach

ANATOMICAL DIAGNOSIS

Malignant lymphoma, reticulum-cell-sarcoma type, of testis, stomach and retroperitoneal lymph nodes

PATHOLOGICAL DISCUSSION

DR CASTLEMAN We received a small biopsy from the stomach and the entire right testis. Grossly the testis had almost the same consistence of a normal testis, but on section the surface appeared to be uniformly replaced by a soft, pinkish-gray, obviously neoplastic tissue. Microscopically, however, the tubules of the testis persisted, and the tumor cells infiltrated between them without destroying them. In other words, the entire organ was not replaced by the tumor, but the tumor was interspersed between tubules, a finding very much against a primary tumor of the testis and more in keeping with a lymphoma, which is what this lesion was. It was a very rapidly growing lymphoma of the reticulum-cell-sarcoma type, and the biopsy from the stomach showed a similar appearance. We believe that lymphomas arise independently in various parts of the body rather than metastasize from one place to another. One can argue that this was primary in the stomach and metastasized to the testis, but it is more likely that it arose independently in the stomach, retroperitoneal lymph nodes and testis and apparently now in both testes.

A PHYSICIAN Are reticulum-cell sarcomas resistant to x-ray therapy?

DR SCHULZ Ordinarily, no. Perhaps the reason why the lesion has not changed is that a sufficient amount of time has not elapsed.

DR CASTLEMAN Are you using the 200 K V or the million-volt machine?

DR SCHULZ The million-volt machine — it does not matter which one uses as long as it gets to the tumor. Of course, a larger dose can be given with the million-volt machine with less skin damage.

DR DONALD S KING How often do you see a lymphoma of the testicle?

DR CASTLEMAN We have seen 2 cases, I believe, in which lymphoma was limited to the testicle, and I believe we have seen several cases with extensive disease throughout the body in which the testes were also involved.

DR KING It is uncommon, I should say.

DR CASTLEMAN Yes. I believe that when lymphoma does occur in the testis, it is usually this type of lymphoma. I wonder if the immature cells seen in the peripheral blood were monocytes, which would fit in with this type of disease.

THE SECOND MILE

THE way of the physician must in many respects be as pastoral as is that of the minister. Without the necessity of conforming to stated spiritual requirements, he, too, must act as guide and counselor, and seek to interpret life's enigmas when the need is greatest. For him, however, there is no congregation, his concern is primarily for the one, and only secondarily for the ninety and nine. Providing guidance, as he must, through the entire span of life, he attends man's entrance into it and supports his passage from it.

The true physician must introduce life to the world, moreover, with an assurance of its fruitfulness and, in complementary relation to the pastor, must many times help others to survey the

dark and lonely valley in serenity and without fear. Having accepted the charge of going one mile with his neighbor he must then go with him twain. As Osler remarked in his Ingersoll Lecture on the Immortality of Man,* delivered at Harvard University in 1904, "The physician's work lies on the confines of the shadow-land, and it might be expected that, if to any, to him would come glimpses that might make us less forlorn."

In that same essay the Baltimore physician commented on the records he had kept of some five hundred deathbeds, describing the apparent sensations of the dying although a small number suffered bodily pain or distress, very few indeed showed mental apprehension or terror. "The great majority gave no sign one way or the other, like their birth, their death was a sleep and a forgetting."

It is in the anticipation of death, then, rather than in the experiencing of it that man is particularly troubled, and this concern, with perhaps the majority of men, is as much over leaving the imperfect but familiar known, as it is over entering the unknown. Still, those of faith can better face that future with fortitude or even joy than can those who lack such transcendent strength.

It is in furnishing guidance down this last and lonely mile, however it may be numbered, that the true physician must develop and exercise one of his most valued skills. This is a skill that can be learned only through the lessons of experience, of compassion, of suffering with others, and of some personal compromise that has been effected between the known and the unknown. Lacking this skill and some form of religious belief, the doctor is only half a doctor — a guide for the first mile only.

All cannot have the supporting strength of a belief in a hereafter, but all can at least have hope and hopeful guidance when the lights grow dim, despite Osler's further statement: "The hopes and fears which make us men are inseparable, and this wine-press of Doubt each one of you must tread alone." This hope can, perhaps, be built up beyond man's fears, and bring each "to the opinion of Cicero, who had rather be mistaken with Plato than be in the right with those who deny altogether the life after death, and this is my own *confessio fidei*."

*Osler W. *Science and Immortality. The Ingersoll Lecture 1904*. 54 pp. Boston and New York: Houghton Mifflin Company, 1904.

STREPTOMYCIN-DEPENDENT BACTERIA

IN THE course of studies on the development of streptomycin resistance by meningococci during subcultures on streptomycin-containing culture plates, Miller and Bohnhoff^{1, 2} observed the development of two types of variants. One, which they called Type A, appeared in approximately equal numbers for any given strain on all concentrations of the antibiotic, but the number of colonies per plate varied from strain to strain. It differed from the original culture in size and color of the colony and in being resistant to streptomycin in vitro and in vivo, but it multiplied on any medium that supported the growth of normal meningococci. It was as virulent for mice as the original culture from which it arose, and in animals it produced infection against which maximal doses of streptomycin afforded no protection.

Colonies of the second, or Type B, variant had one characteristic in common: they required streptomycin for reproduction in vitro and in vivo. This variant was not virulent for mice, in that mucin suspensions of the culture failed to produce infection on intraperitoneal inoculation as the parent strain did. However, mice inoculated in the same manner and treated with adequate amounts of streptomycin developed fatal meningococcal sepsis, and organisms could be cultured from the heart's blood on streptomycin-containing mediums but not on duplicate cultures on streptomycin-free mediums. The Type B colonies varied in size and color, depending on the concentration of streptomycin supplied.

Streptomycin-resistant and streptomycin-dependent variants have also been obtained by Paine and Finland^{3, 4} from sensitive strains of a variety of different pathogenic organisms, including *Staphylococcus aureus*, *Escherichia coli*, *Proteus morgani*, *Pseudomonas aeruginosa* and *Klebsiella pneumoniae*, and Yegian and Budd⁵ obtained similar variants from a strain of *Mycobacterium ranae*, which is not a pathogenic organism. The former authors found that their truly resistant variants retained this characteristic on repeated subculture, either in the presence of streptomycin or in its absence, whereas prolonged incubation of the dependent organisms

in streptomycin-containing mediums gave rise to either predominantly resistant or predominantly sensitive progeny, depending on the concentration of streptomycin contained in the medium. In most of these organisms, furthermore, there was little or no difference in the morphologic and cultural characteristics of the dependent and resistant variants, provided that an adequate concentration of streptomycin was present in the dependent variant.

Of additional interest is the fact that the dependent variant of *Mycobacterium ranae* was found by Yegian and Budd to grow in the presence of streptomycin in medium containing 100 mg per 100 cc of sulfathiazole, whereas the parent strain and the streptomycin-resistant (Type A) variant were both inhibited by 1 mg per 100 cc of sulfathiazole. Their culture had not previously been exposed to sulfathiazole.

It is well recognized that the replacement of a streptomycin-sensitive by a streptomycin-resistant flora in the course of therapy renders useless any further treatment with streptomycin. The possibility that streptomycin-dependent organisms may arise and be maintained during streptomycin treatment, however, may constitute a more serious hazard. Although the continued streptomycin therapy may do no good against the usual streptomycin-resistant organisms, it is not likely to aggravate the infection or do any harm other than that resulting from the toxic effects of the antibiotic. The maintenance of streptomycin therapy in the presence of streptomycin-dependent organisms, on the other hand, might actually sustain or aggravate an infection by permitting the continued multiplication of these organisms when they would not otherwise multiply were the streptomycin therapy stopped. Furthermore, the appearance of streptomycin-dependent organisms in vitro is always accompanied by the occurrence of much larger numbers of resistant variants, so that, if the same principle is true in vivo, there seems to be no further reason for continuing streptomycin therapy after dependent variants have made their appearance.

The finding of streptomycin-dependent variants, apparently developing during treatment with streptomycin, has now been reported by two separate groups of observers.^{6, 7} Spendlove et al.⁶

It was as virulent for mice as the original culture from which it arose, and in animals it produced infection against which maximal doses of streptomycin afforded no protection.

Colonies of the second, or Type B, variant had one characteristic in common: they required streptomycin for reproduction in vitro and in vivo. This variant was not virulent for mice, in that mucin suspensions of the culture failed to produce infection on intraperitoneal inoculation as the parent strain did. However, mice inoculated in the same manner and treated with adequate amounts of streptomycin developed fatal meningococcal sepsis, and organisms could be cultured from the heart's blood on streptomycin-containing mediums but not on duplicate cultures on streptomycin-free mediums. The Type B colonies varied in size and color, depending on the concentration of streptomycin supplied.

Streptomycin-resistant and streptomycin-dependent variants have also been obtained by Paine and Finland^{3,4} from sensitive strains of a variety of different pathogenic organisms, including *Staphylococcus aureus*, *Escherichia coli*, *Proteus morganii*, *Pseudomonas aeruginosa* and *Klebsiella pneumoniae*, and Yegian and Budd⁵ obtained similar variants from a strain of *Mycobacterium ranae*, which is not a pathogenic organism. The former authors found that their truly resistant variants retained this characteristic on repeated subculture, either in the presence of streptomycin or in its absence, whereas prolonged incubation of the dependent organisms

in streptomycin-containing mediums gave rise to either predominantly resistant or predominantly sensitive progeny, depending on the concentration of streptomycin contained in the medium. In most of these organisms, furthermore, there was little or no difference in the morphologic and cultural characteristics of the dependent and resistant variants, provided that an adequate concentration of streptomycin was present in the dependent variant.

Of additional interest is the fact that the dependent variant of *Mycobacterium ranae* was found by Yegian and Budd to grow in the presence of streptomycin in medium containing 100 mg per 100 cc of sulfathiazole, whereas the parent strain and the streptomycin-resistant (Type A) variant were both inhibited by 1 mg per 100 cc of sulfathiazole. Their culture had not previously been exposed to sulfathiazole.

It is well recognized that the replacement of a streptomycin-sensitive by a streptomycin-resistant flora in the course of therapy renders useless any further treatment with streptomycin. The possibility that streptomycin-dependent organisms may arise and be maintained during streptomycin treatment, however, may constitute a more serious hazard. Although the continued streptomycin therapy may do no good against the usual streptomycin-resistant organisms, it is not likely to aggravate the infection or do any harm other than that resulting from the toxic effects of the antibiotic. The maintenance of streptomycin therapy in the presence of streptomycin-dependent organisms, on the other hand, might actually sustain or aggravate an infection by permitting the continued multiplication of these organisms when they would not otherwise multiply were the streptomycin therapy stopped. Furthermore, the appearance of streptomycin-dependent organisms in vitro is always accompanied by the occurrence of much larger numbers of resistant variants, so that, if the same principle is true in vivo, there seems to be no further reason for continuing streptomycin therapy after dependent variants have made their appearance.

The finding of streptomycin-dependent variants, apparently developing during treatment with streptomycin, has now been reported by two separate groups of observers.^{6,7} Spendlove et al.⁶

isolated a streptomycin-dependent strain of *Mycobacterium tuberculosis* on the ninety-sixth day of streptomycin treatment. This was discovered during routine streptomycin sensitivity testing of the strains when it was noted that growth was poor in the control tube without streptomycin while it was abundant in all tubes containing streptomycin in concentrations ranging from 1 to 1000 microgm per cubic centimeter. This patient's infection showed rapid progression during the course of streptomycin therapy, and no striking change occurred after this treatment was stopped.

In this case, a strain of tubercle bacillus isolated three months later had similar characteristics, it failed to grow in mediums without streptomycin and grew in the same mediums when concentrations of streptomycin from 1 to 1000 microgm per cubic centimeter were added. If the findings as reported are correct they suggest either that the patient was supplying some factor that served in place of the streptomycin in supporting the multiplication of the dependent variants or that some of these variants arose during the course of the streptomycin treatment and persisted without multiplying in the patient after the antibiotic was discontinued.

More recently, Miller⁷ looked for streptomycin-resistant or streptomycin-dependent organisms in animals and in patients under treatment with streptomycin. He gave normal rabbits and mice large doses of streptomycin and made periodic cultures of the pharynx and large bowel on mediums containing 400 microgm of streptomycin per cubic centimeter. After a week both Type A and Type B variants were recovered in these animals. He made similar pharyngeal cultures on patients who were being treated with streptomycin and obtained positive cultures in 98 per cent of these patients by the thirteenth day of treatment. In addition, about 10 per cent of patients not receiving streptomycin and 4 per cent of the staff, students and laboratory personnel yielded a few organisms in similar cultures. The highest incidence of positive cultures among controls — 21 per cent — was obtained from the nurses and maids working on the wards. All the strongly positive cultures were from the nurses who were caring for patients receiving streptomycin. The organisms recovered from these cul-

tures were predominantly the truly resistant or Type A variants, but a certain proportion were streptomycin-dependent or Type B.

These findings suggest that streptomycin-resistant organisms that developed in the throats of the treated patients were transferred to the nurses who looked after them. Although most of the organisms obtained in this study were presumed to be nonpathogenic, the possibility of transmitting resistant strains that are pathogenic is clearly evident.

Hobby and Dougherty⁸ have described still another type of streptomycin-resistant variant capable of multiplying in an aqueous solution of streptomycin that contains no other added nutrients.

MEDICAL DEFENSE BOTTLENECK

Doctor shortage in the armed forces is no longer news, but its importance is increasing so rapidly that the Secretary of Defense recently called a press conference to issue an urgent warning. He gave facts, stated alternatives and disclosed plans.

Owing chiefly to the expiration of ASTP and V-12 tours of duty, the armed forces, already numbering almost 1,700,000, will lack 2760 medical and dental officers by July and by December will lack 3600 "Normal procurement channels" — that is, the present volunteer system — offer the only means of making good this shortage, and January's record of 30 new Medical Corps and 20 new Dental Corps commissions may be taken as a fair sample of its inadequacy. "We are in grave trouble and it is getting worse" according to a memorandum to the Secretary of Defense from the Air Secretary, and "In the Army the situation is

more serious than in the Air Force' adds the Under Secretary of the Army. Failure to mention the Navy does not imply that the Navy is any more fortunate. Medical manpower is the bottleneck of the armed-forces expansion program, and a real solution must be found.

Four alternatives appear, of which only the fourth is presently favored by the Department of Defense. One is to ask for a draft of physicians and dentists in the numbers needed, the second is to request reserve officers who served in World War II to return to active duty, the third is to require the men now on active duty to remain after their time of service is up, and the fourth is to appeal to the 15,000 men who have not served, all of whom were deferred during the war and some of whom (8000) received part or all of their professional training at Government expense. The Secretary of Defense made the following statement:

I believe these 15,000 men who saw no service overseas and who were not exposed to the rigors of war will themselves recognize our right to appeal to them to make a contribution in this emergency. In a democracy, this procedure is fair, equitable, and just. As Americans, I am confident that they will recognize their obligations if they are acquainted with the facts.

The Secretary is taking steps to implement these beliefs. By personal letter he will invite those trained at Government expense to accept commissions through local professional leaders he will appeal to those who were deferred from the draft, and excused from combat to complete their professional education at their own expense, to apply for commissions, and by a publicity campaign he will enlist nation-wide support and understanding of the Defense Department's position.

An essential part of this program has been assigned to the Armed Forces Medical Advisory Committee composed of the surgeons general of the Army and Navy, the Air Surgeon and eleven distinguished civilian doctors under the chairmanship of Mr. Charles P. Cooper. Their task is to restore public confidence by eliminating professional manpower waste in the armed forces, thus removing the most serious stumbling block to volunteer service. It can be accomplished by merging the strength of the three services by defining and streamlining their workload, by raising professional standards

and by ensuring that "in so far as possible, each volunteer serves in an assignment commensurate with his professional skill and ability" so that his one or two years of military service will not be time lost. Should this immense undertaking succeed — and there is reason to believe that it will — a further debt of gratitude will be owed to the committee members, who, both in the regular components and as volunteers, have already rendered distinguished services to their country during the war.

Should this enlightened volunteer system fall short of meeting the manpower crisis, there will be no alternative but the draft, and whatever one may think of its fairness and its efficiency there will be no further possible doubt of its necessity. "For want of a nail the shoe was lost, for want of a shoe the horse was lost, for want of a horse the rider was lost" is the way *Poor Richard's Almanac* put it almost two hundred years ago. The modern version might read for want of medical officers the armed forces were lost, for want of armed forces the peace was lost, and for want of the peace western civilization was lost. Whatever the price of success, one way or another it must be achieved now, for the price of another failure is too great for humanity to contemplate.

STUDY OF MATERNAL DEATHS

THE attention of fellows of the Massachusetts Medical Society and other readers of the *Journal* who reside and practice in Massachusetts is directed to the letter from Dr. Gillespie published elsewhere in this issue.

A five-year program has been initiated by the Committee on Maternal Welfare of the Massachusetts Medical Society, in conjunction with the Division of Maternal and Child Health of the Massachusetts Department of Public Health, for the study of all maternal deaths in the Commonwealth, whether they occur at home or in the hospital. All deaths within three months of the termination of pregnancy are to be included.

The purposes of the study are to determine exactly the total number of such deaths each year in the Commonwealth and the percentages at some

and in the hospital, to determine as exactly as possible the causes of all such deaths and their preventability, and to publish each year the number and causes, the findings of the study and the recommendations of the committee, both general and specific, for the improvement of maternal care

So far as available statistics are concerned it is known that there were approximately 125 maternal deaths in the hospitals of the Commonwealth in 1948. It is not known with any exactness how many of the deaths at home took place before or after delivery and might be accountable to the pregnancy, nor is it known how many mothers died of contributory causes that might not be obstetrically listed. Thus, in the autopsy of sudden deaths suggestive of pulmonary embolism and thrombosis, the attention of physicians and pathologists is called to the possibility of amniotic-fluid emboli and the methods employed to prove such a diagnosis.*

The committee, in order that these important data may be obtained, strongly urges all physicians to report promptly to either physician mentioned in the communication all maternal deaths, wherever they may occur.

MASSACHUSETTS MEDICAL SOCIETY

DEATHS

CHISHOLM — Miles D Chisholm, M.D., of Westfield, died on December 19. He was in his seventy-second year.

Dr Chisholm received his degree from University College of Medicine, Richmond, Virginia, in 1900. He was formerly city physician in Westfield and was a member of the staff of the Noble Hospital. He was a fellow of the American College of Surgeons and the American Medical Association.

His widow, a daughter and two grandchildren survive.

CROSS — Albert E Cross, M.D., of Worcester, died on November 6. He was in his seventy-seventh year.

Dr Cross received his degree from Boston University School of Medicine in 1900. He was a member of the board of governors of the Hahnemann Hospital and was a member of the American Academy of Ophthalmology and Otolaryngology and the New England Ophthalmological Society and a fellow of the American Medical Association.

His widow and two daughters survive.

HEALY — James C Healy, M.D., of Boston, died on November 19. He was in his forty-seventh year.

Dr Healy received his degree from Tufts College Medical School in 1927. He was assistant professor of pharmacology at Tufts College Medical School.

His widow, a son and a daughter survive.

McKENZIE — John R McKenzie, M.D., formerly of Cambridge, died on March 16. He was in his eighty-second year.

Dr McKenzie received his degree from Harvard Medical School in 1894. He was formerly a member of the staffs of

Holy Ghost Hospital for Incurables, Cambridge, and Worcester City, Boston City and Boston Lying-in hospitals. He was a fellow of the American Medical Association.

His widow and two sisters survive.

McQUADE — Lewis S McQuade, M.D., of Quincy, died on March 10. He was in his sixty-seventh year.

Dr McQuade received his degree from Tufts College Medical School in 1907.

A sister survives.

NEWELL — Franklin S Newell, M.D., of Boston, died on March 3. He was in his seventy-eighth year.
